Introduction

- Companies seem to have no problem producing Au-in-calcrete anomalies
- BUT
- The **BIG** question:
 - Can we rank these and make them more effective???

Tunkillia

- ENORMOUS Au-in-calcrete anomaly
 - ~ 20 km at > 10 ppb Au
- Extensive drilling \$\$\$ (>\$15 million)
 - defined small discrete zones of mineralisation

Introduction

- What can we learn from the Tunkillia experience?
- Can we use this knowledge to improve the success rate of other Au-in-calcrete anomalies in the area?

What did we do?

- Regolith-Landform mapping
- Sampled 3 transects across:
 - 1. Au-in-calcrete anomaly over mineralisation
 - 2. Au-in-calcrete anomaly over barren bedrock
 - 3. background
- Samples assayed for 53 element suite

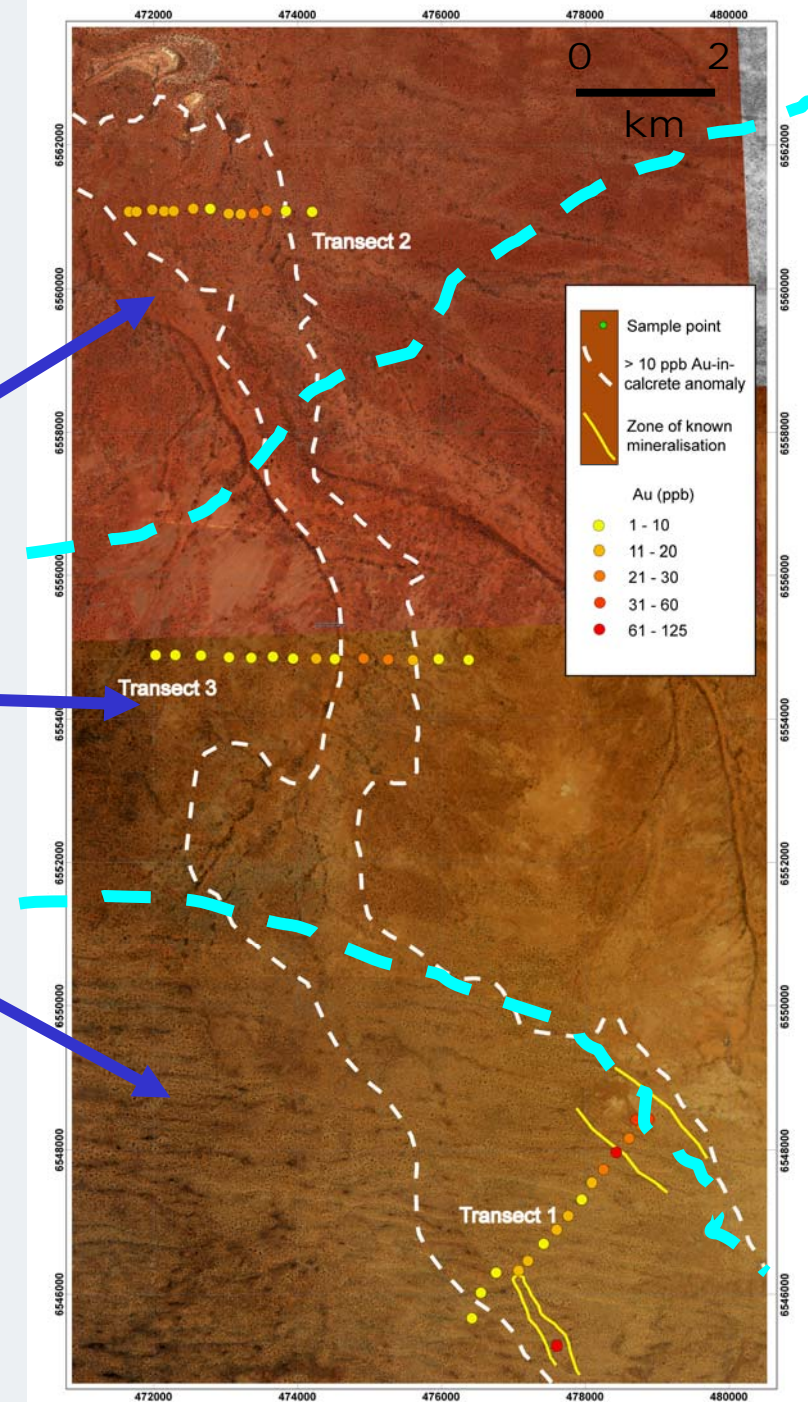

REGOLITH-LANDFORM MAPPING

CRCLEME

Regolith-Landform mapping

- Main landform zones
 - Depositional
 - Erosional
 - Dunefield

What the
completed
regolith-landform
map looks like

Southern transect

- Dunefield

Central transect

- Erosional plains

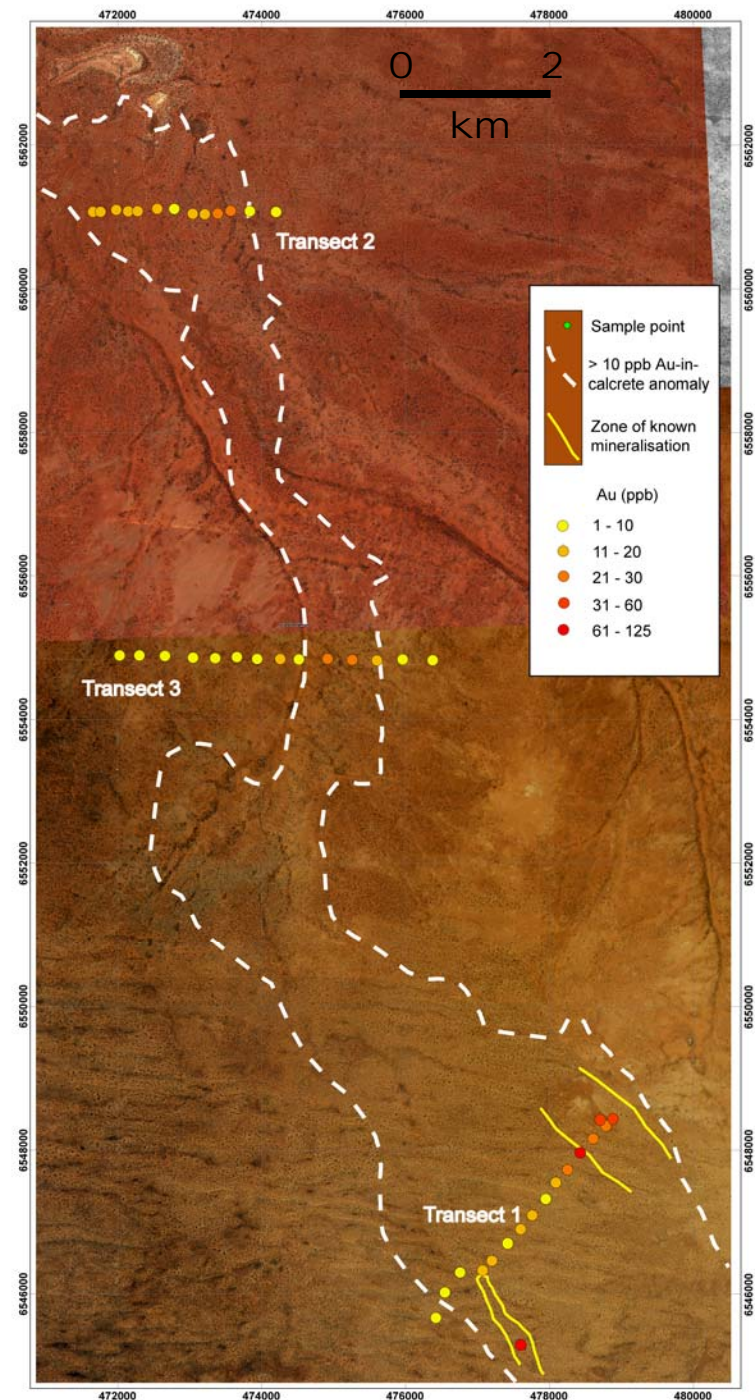

Northern transect

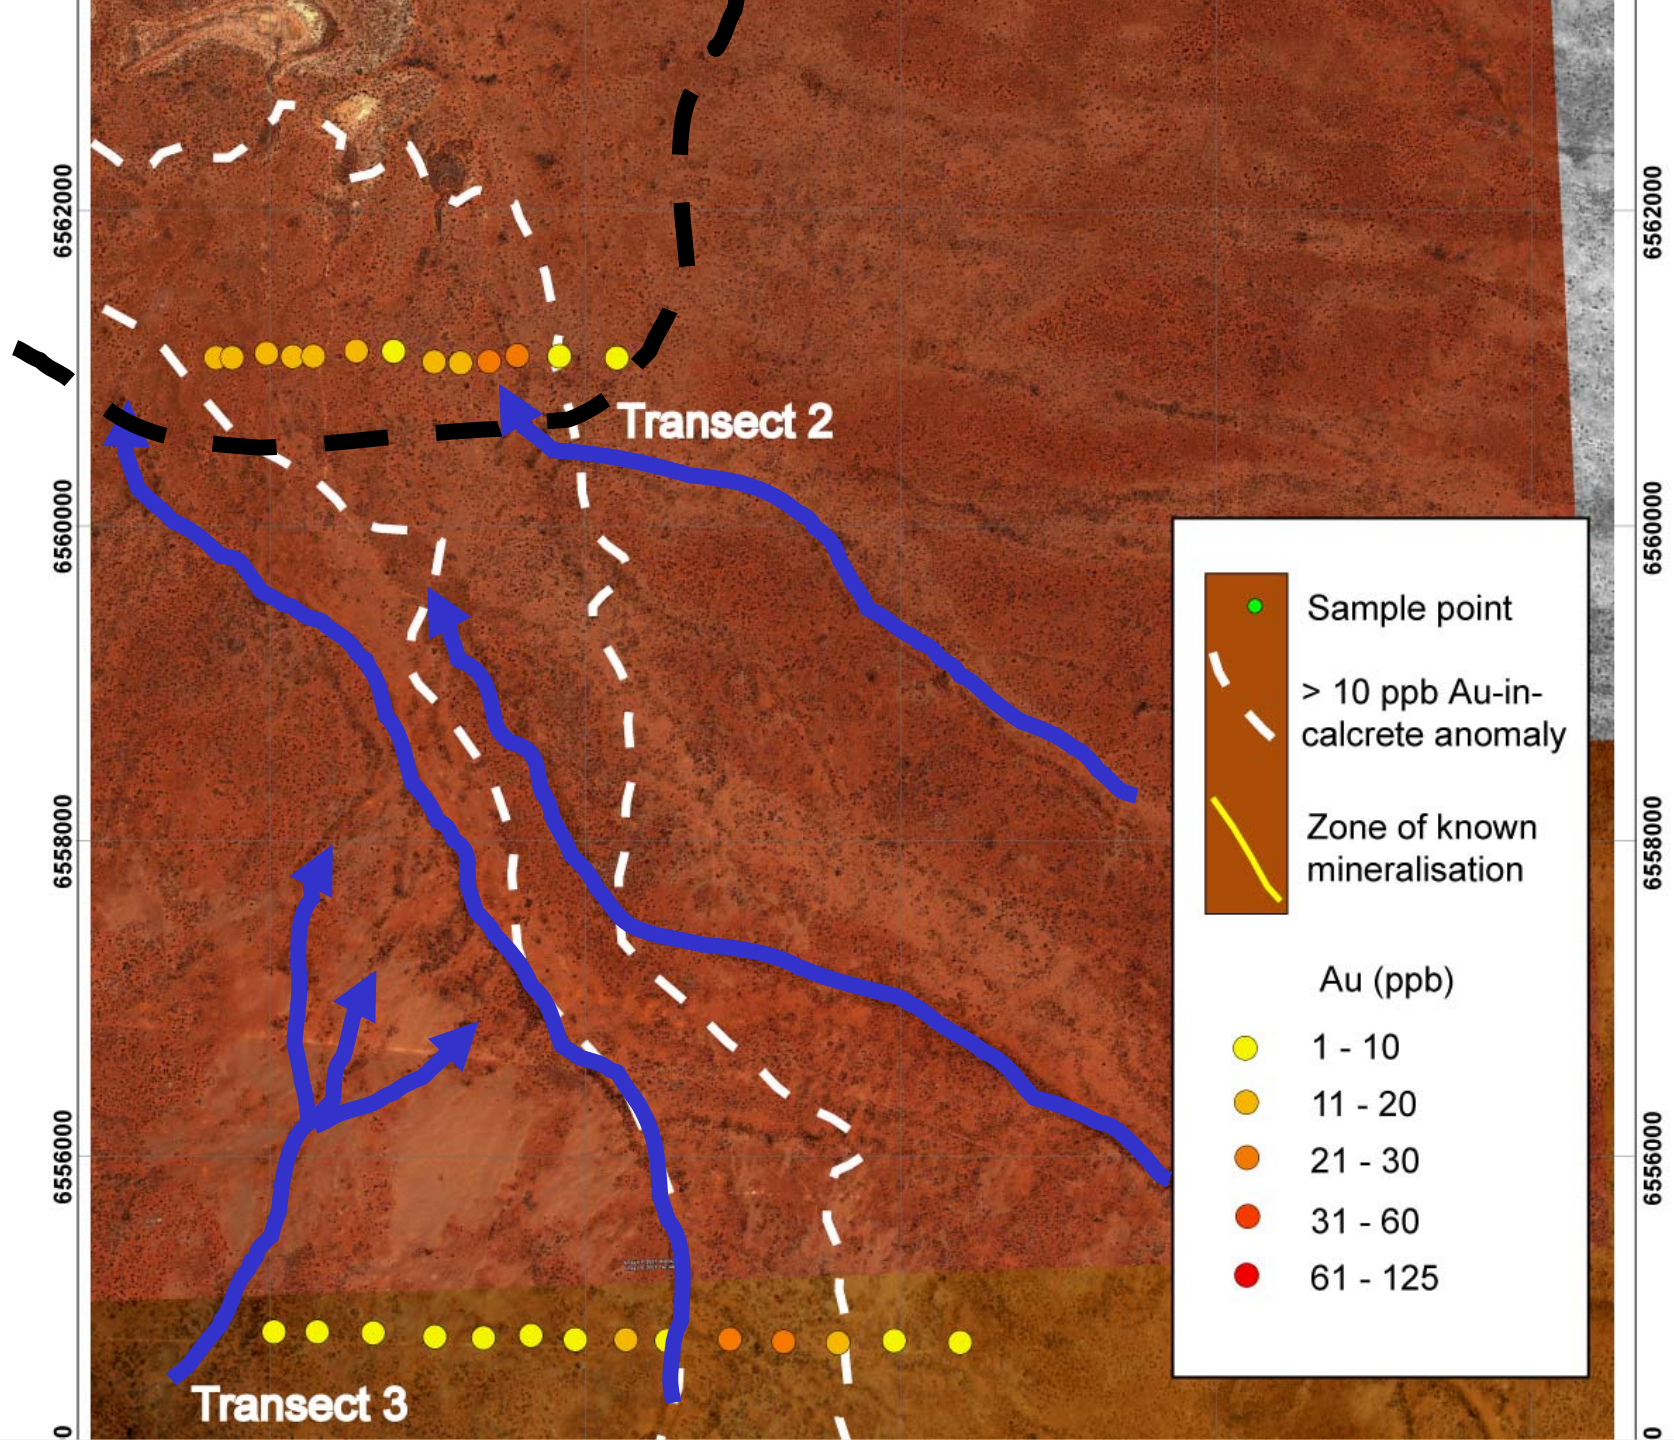

- Depositional plains & ephemeral lakes

What regolith-mapping revealed

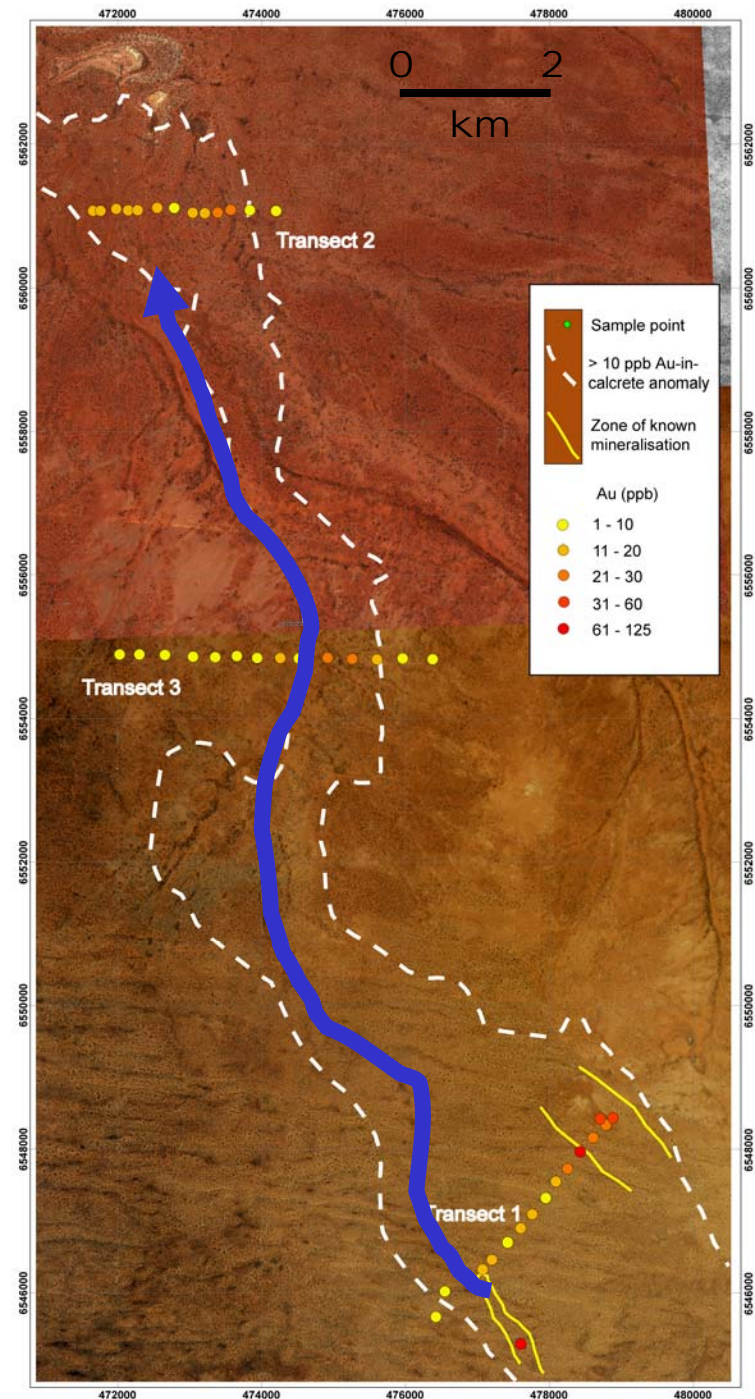

Points to note

- Palaeodrainage extends beneath sand dunes
- Au-in-calcrete anomaly shape follows palaeo- and contemporary drainage system

A vertical strip on the left side of the slide shows a microscopic view of regolith carbonates. It features various circular and oval-shaped structures with concentric rings of different colors, including brown, tan, and dark grey, set against a lighter, speckled background.

REGOLITH CARBONATES AND ASSAY RESULTS

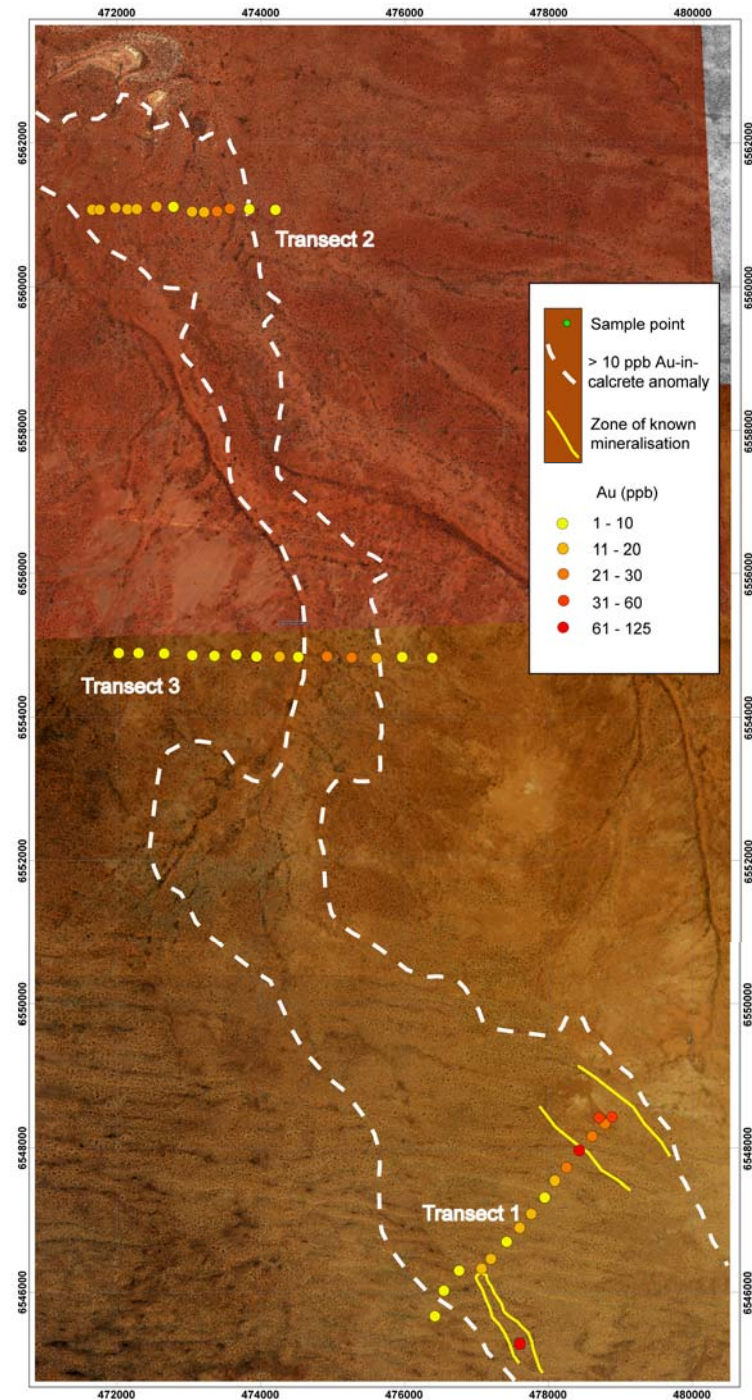

When is a calcrete a calcrete?

- Southern transect
 - Calcareous red sand
 - 0.74 – 9.7% CaO, ~0.8 m deep
 - Nodules with hardpan
 - 8.5 – 39.4% CaO, ~0.5 m deep
- Central transect
 - Predominantly hardpan
 - 20.7 – 42.9% CaO, ~0.2 m deep
- Northern transect
 - Calcareous sand and nodules
 - 4.0 – 9.1% CaO, ~0.6 m deep

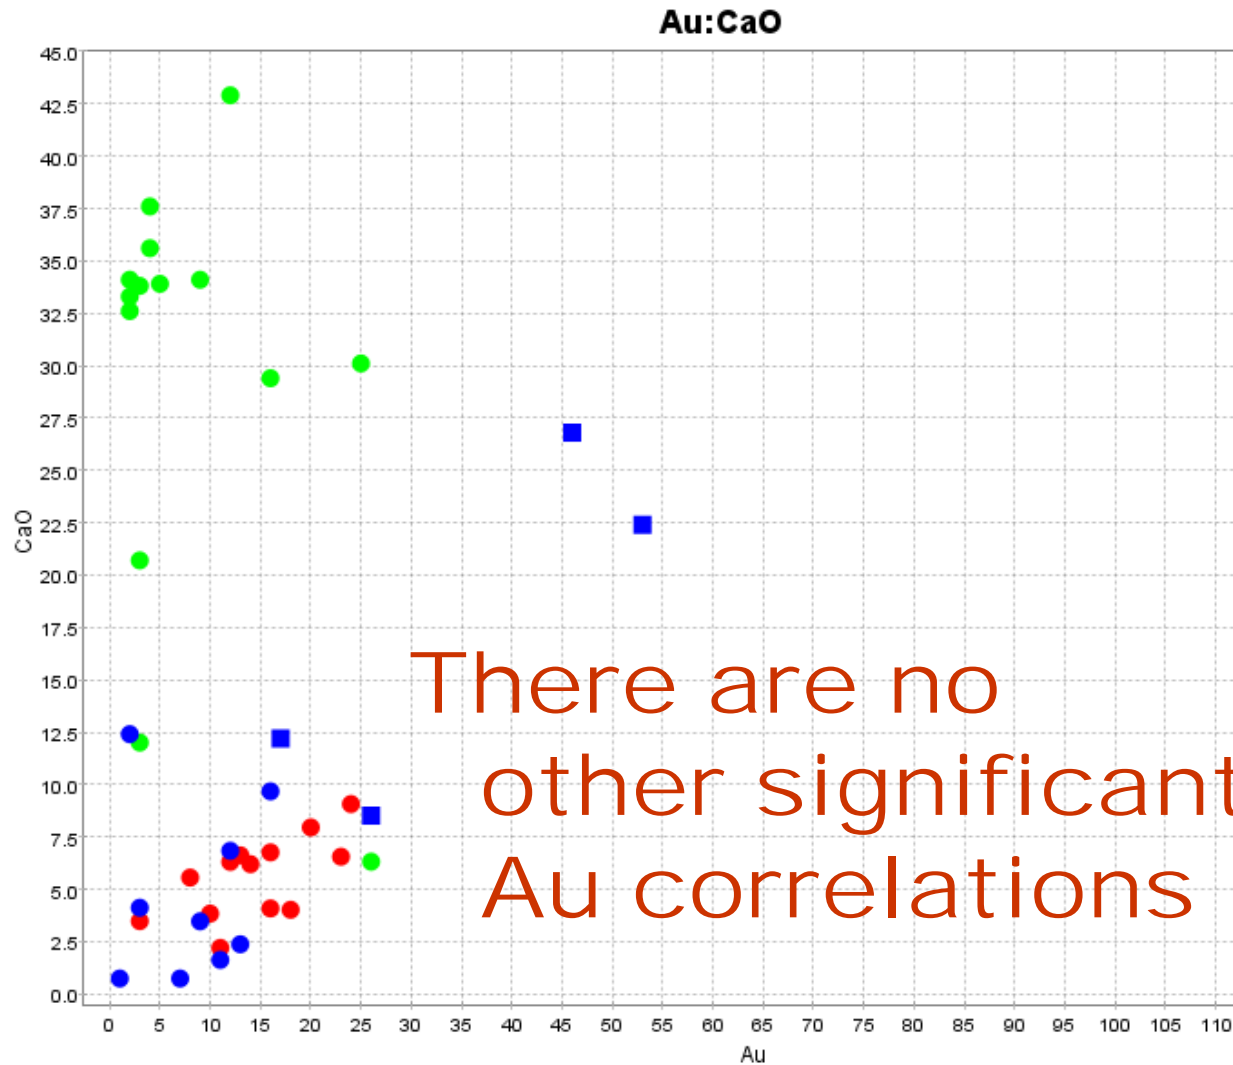

Transect Au assays

- New results indicate
 - Repeatability of company work
 - Au finely dispersed

Assay results

- Ca & Au correlation

Assay results

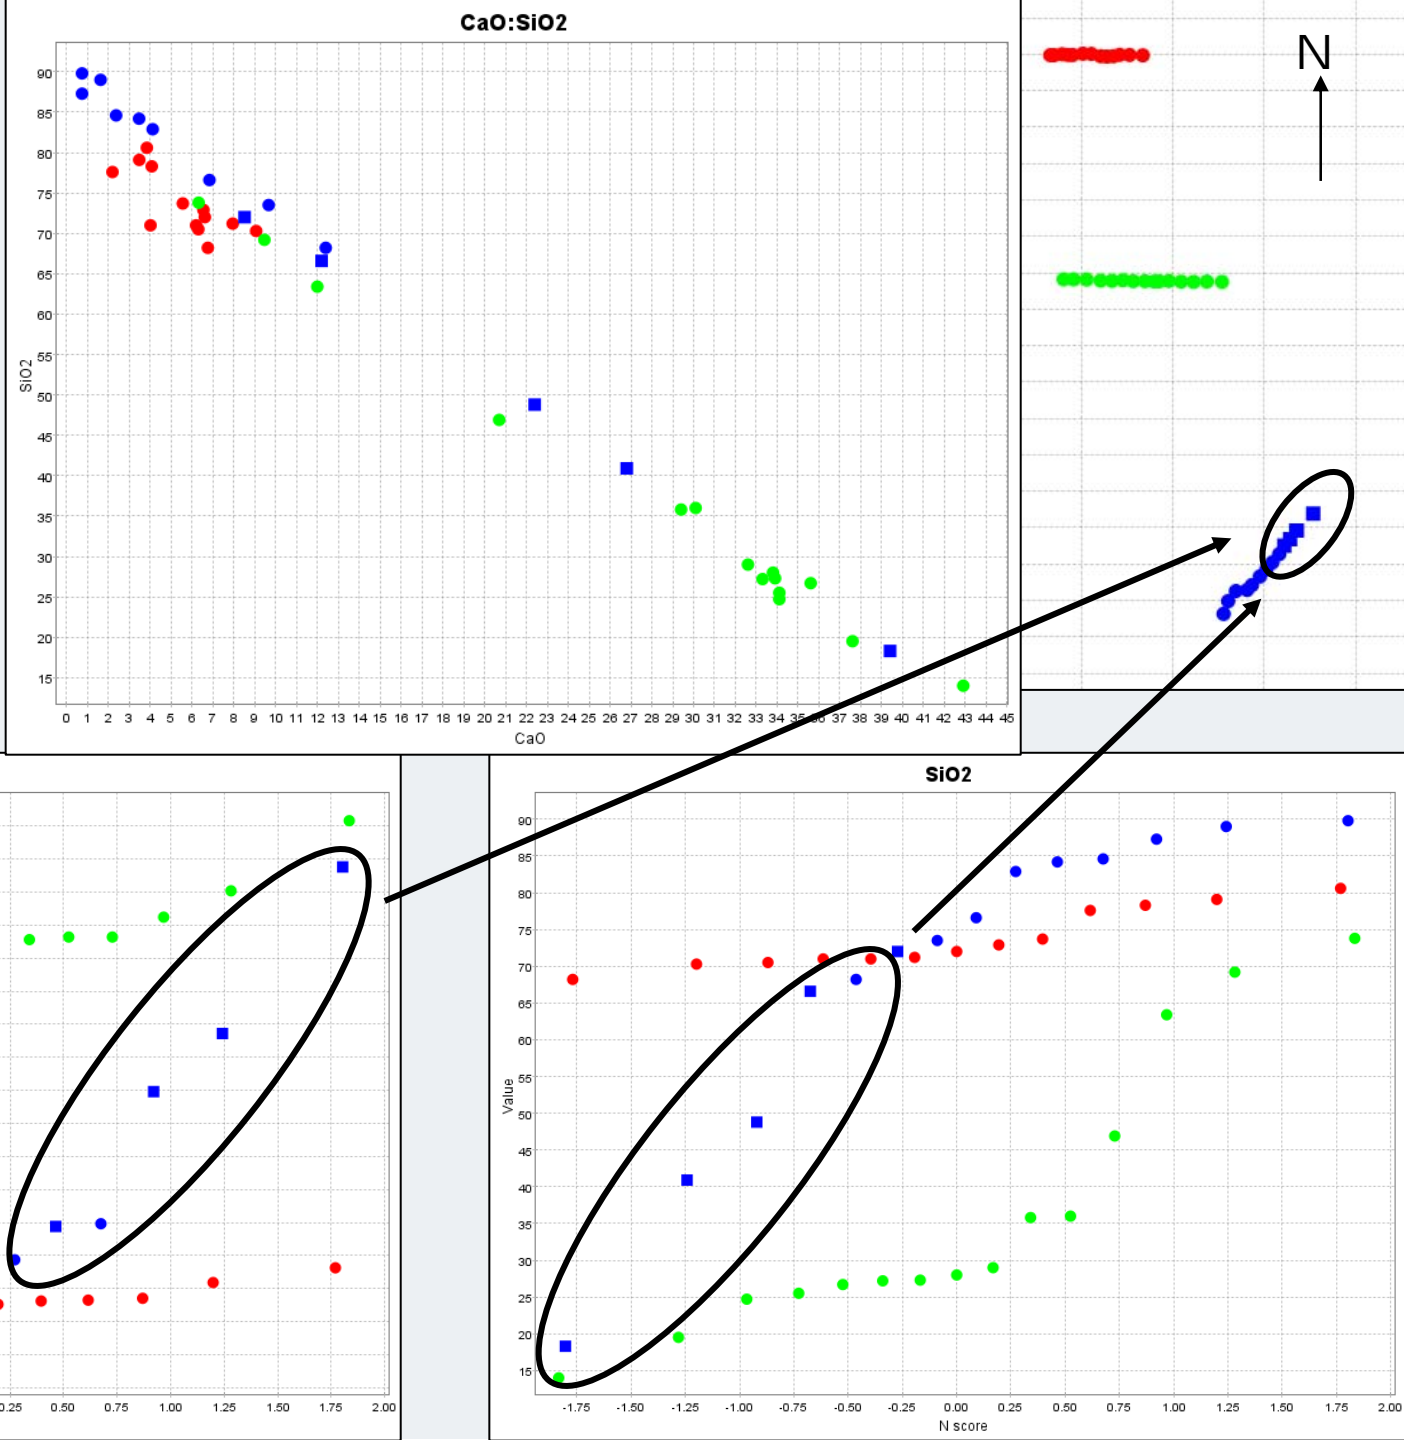

- Au distribution

CRCLEME

Assay results

Si and Ca

A Warning!

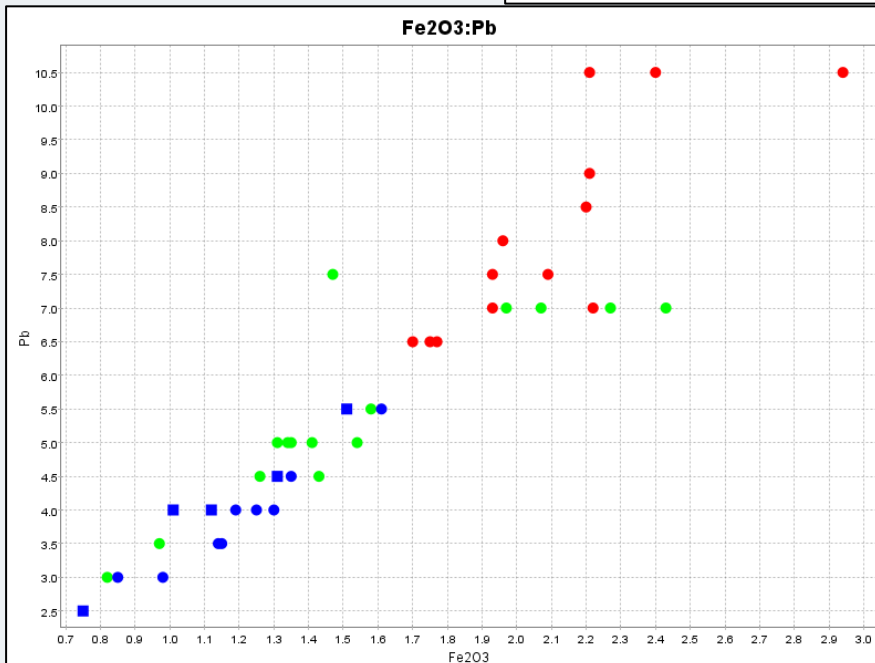

~~"Apparent"
highs over
mineralisation for
several ele~~

Due to low
values along
southern end
of transect

Assay results

Correlations
between
Fe, Pb and
Zn

Assay results

Cu is the only element that is high over both zones of mineralisation

Assay results

- REE
 - Strongly correlated
 - Low along southern transect
- No single element high over mineralisation alone
- Analysis is ongoing.....

WHAT DOES ALL THIS MEAN SUGGESTED MODEL

Things to think about

- Not all calcretes are calcrete!
 - Samples range from <1% to >40% CaO
- Highs may be due to anomalous lows
- Higher Si content along transect 1 masks other element concentrations and confuses the analysis

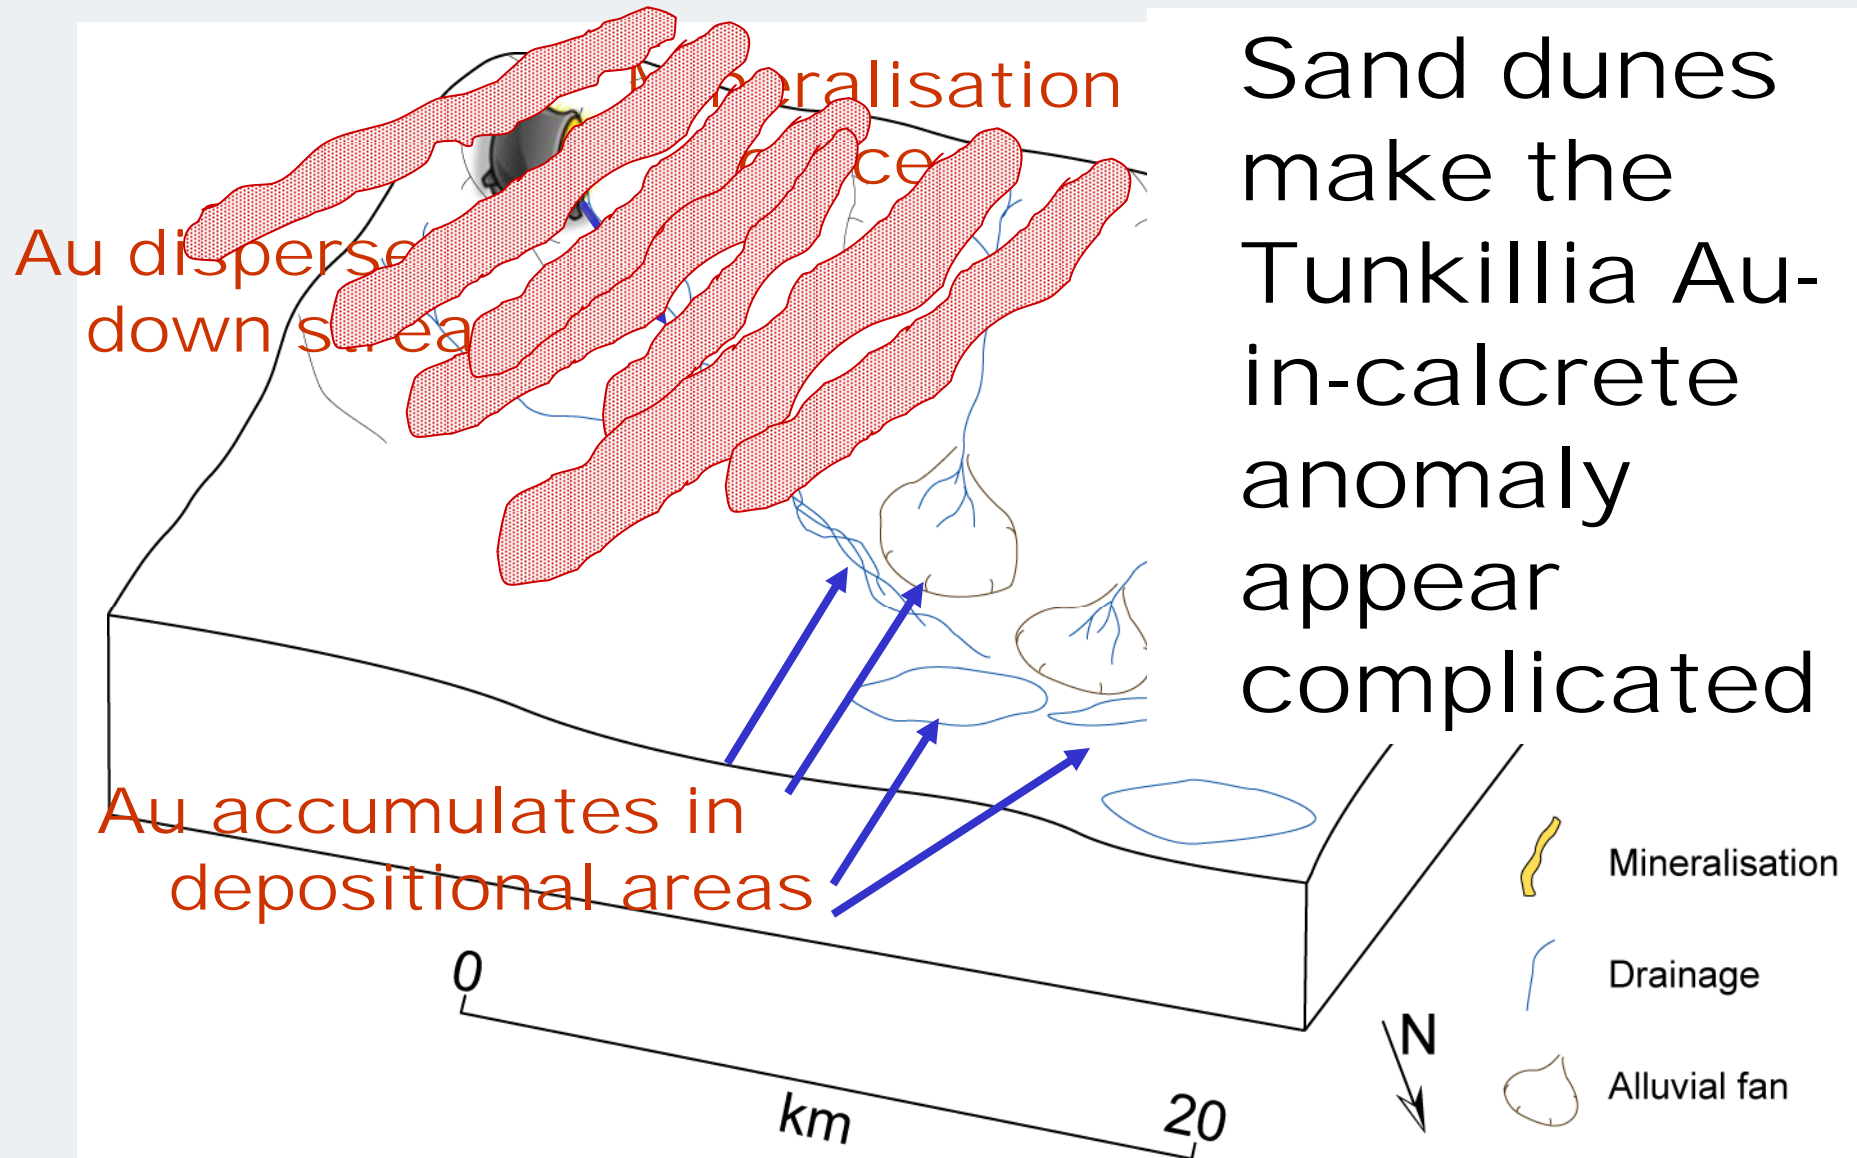

Things to think about

- Majority of elements are abundant in the north
 - reflects dispersion and deposition
- What is an anomalous Au value
 - Should we consider raising the threshold?
 - Probability plot shows >30 ppb for Tunkillia
- Finally... It is not difficult to explain the large Au-in-calcrete.....

Proposed model

Sand dunes make the Tunkillia Au-in-calcrete anomaly appear complicated

Take home point

- Understanding landscape processes can reveal more than you would expect
