RESEARCH ARISING FROM CSIRO/AMIRA REGOLITH GEOCHEMISTRY PROJECTS 1987-1993

In 1987, CSIRO commenced a series of multi-client research projects in regolith geology and geochemistry which were sponsored by companies in the Australian mining industry, through the Australian Mineral Industries Research Association Limited (AMIRA). The initial research program, "Exploration for concealed gold deposits, Yilgarn Block, Western Australia" (1987-1993) had the aim of developing improved geological, geochemical and geophysical methods for mineral exploration that would facilitate the location of blind, buried or deeply weathered gold deposits. The program included the following projects:

P240: Laterite geochemistry for detecting concealed mineral deposits (1987-1991). Leader: Dr R.E. Smith. Its scope was development of methods for sampling and interpretation of multi-element laterite geochemistry data and application of multi-element techniques to gold and polymetallic mineral exploration in weathered terrain. The project emphasised viewing laterite geochemical dispersion patterns in their regolith-landform context at local and district scales. It was supported by 30 companies.

P241: Gold and associated elements in the regolith - dispersion processes and implications for exploration (1987-1991). Leader: Dr C.R.M. Butt.

The project investigated the distribution of ore and indicator elements in the regolith. It included studies of the mineralogical and geochemical characteristics of weathered ore deposits and wall rocks, and the chemical controls on element dispersion and concentration during regolith evolution. This was to increase the effectiveness of geochemical exploration in weathered terrain through improved understanding of weathering processes. It was supported by 26 companies.

These projects represented "an opportunity for the mineral industry to participate in a multi-disciplinary program of geoscience research aimed at developing new geological, geochemical and geophysical methods for exploration in deeply weathered Archaean terrains". This initiative recognised the unique opportunities, created by exploration and open-cut mining, to conduct detailed studies of the weathered zone, with particular emphasis on the near-surface expression of gold mineralisation. The skills of existing and specially recruited research staff from the Floreat Park and North Ryde laboratories (of the then Divisions of Minerals and Geochemistry, and Mineral Physics and Mineralogy, subsequently Exploration Geoscience and later Exploration and Mining) were integrated to form a task force with expertise in geology, mineralogy, geochemistry and geophysics. Several staff participated in more than one project. Following completion of the original projects, two continuation projects were developed.

P240A: Geochemical exploration in complex lateritic environments of the Yilgarn Craton, Western Australia (1991-1993). Leaders: Drs R.E. Smith and R.R. Anand.

The approach of viewing geochemical dispersion within a well-controlled and well-understood regolith-landform and bedrock framework at detailed and district scales continued. In this extension, focus was particularly on areas of transported cover and on more complex lateritic environments typified by the Kalgoorlie regional study. This was supported by 17 companies.

P241A: Gold and associated elements in the regolith - dispersion processes and implications for exploration. Leader: Dr. C.R.M. Butt.

The significance of gold mobilisation under present-day conditions, particularly the important relationship with pedogenic carbonate, was investigated further. In addition, attention was focussed on the recognition of primary lithologies from their weathered equivalents. This project was supported by 14 companies.

Although the confidentiality periods of the research reports have expired, the last in December 1994, they have not been made public until now. Publishing the reports through the CRC LEME Report Series is seen as an appropriate means of doing this. By making available the results of the research and the authors' interpretations, it is hoped that the reports will provide source data for future research and be useful for teaching. CRC LEME acknowledges the Australian Mineral Industries Research Association and CSIRO Division of Exploration and Mining for authorisation to publish these reports. It is intended that publication of the reports will be a substantial additional factor in transferring technology to aid the Australian Mineral Industry.

This report (CRC LEME Open File Report 31) is a first revision of CSIRO, Division of Exploration Geoscience Restricted Report 232R, first issued in 1992, which formed part of the CSIRO/AMIRA Projects P240A and P241A .

APPENDIX 3

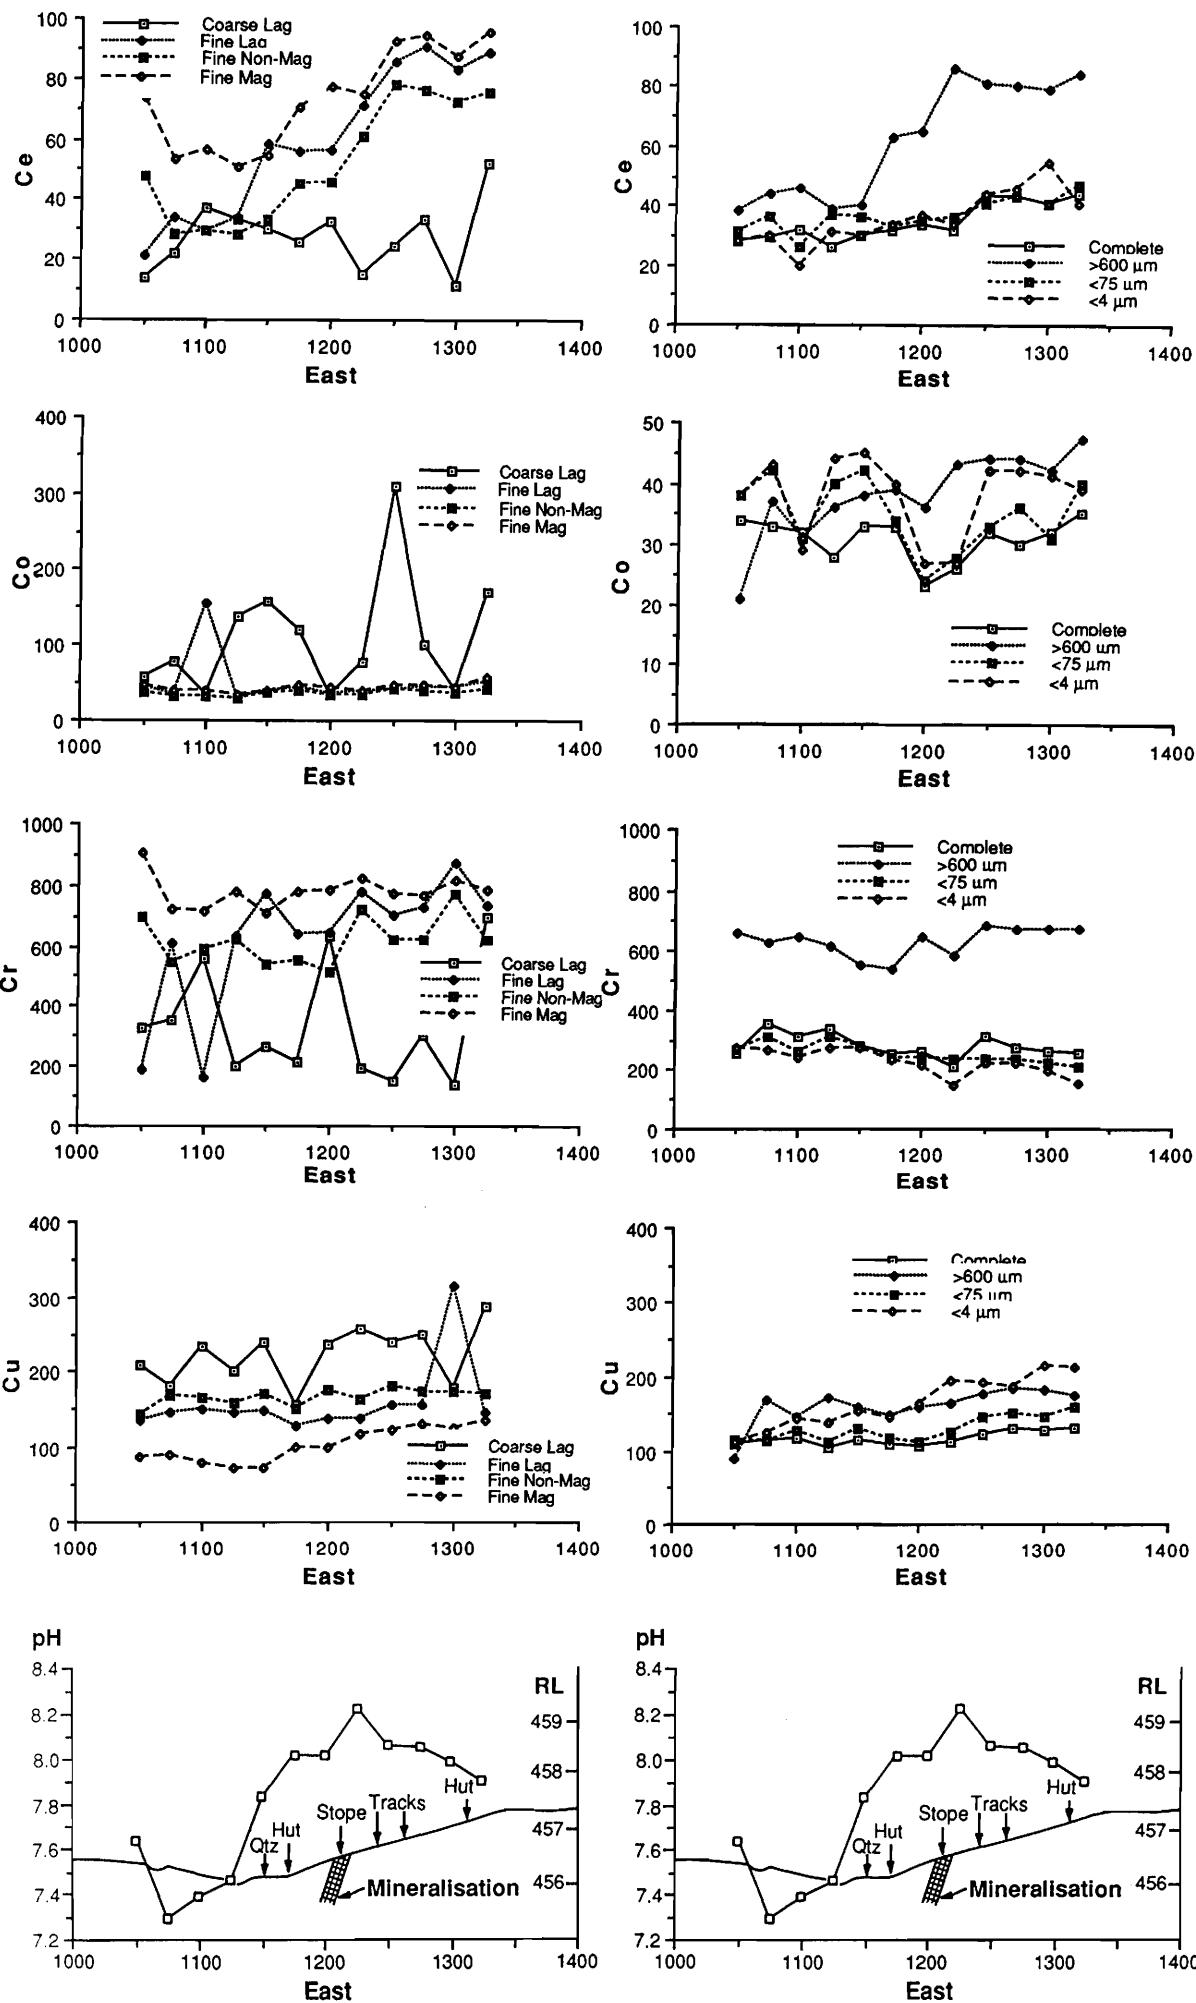

Graphed Soil and Lay Geochemistry

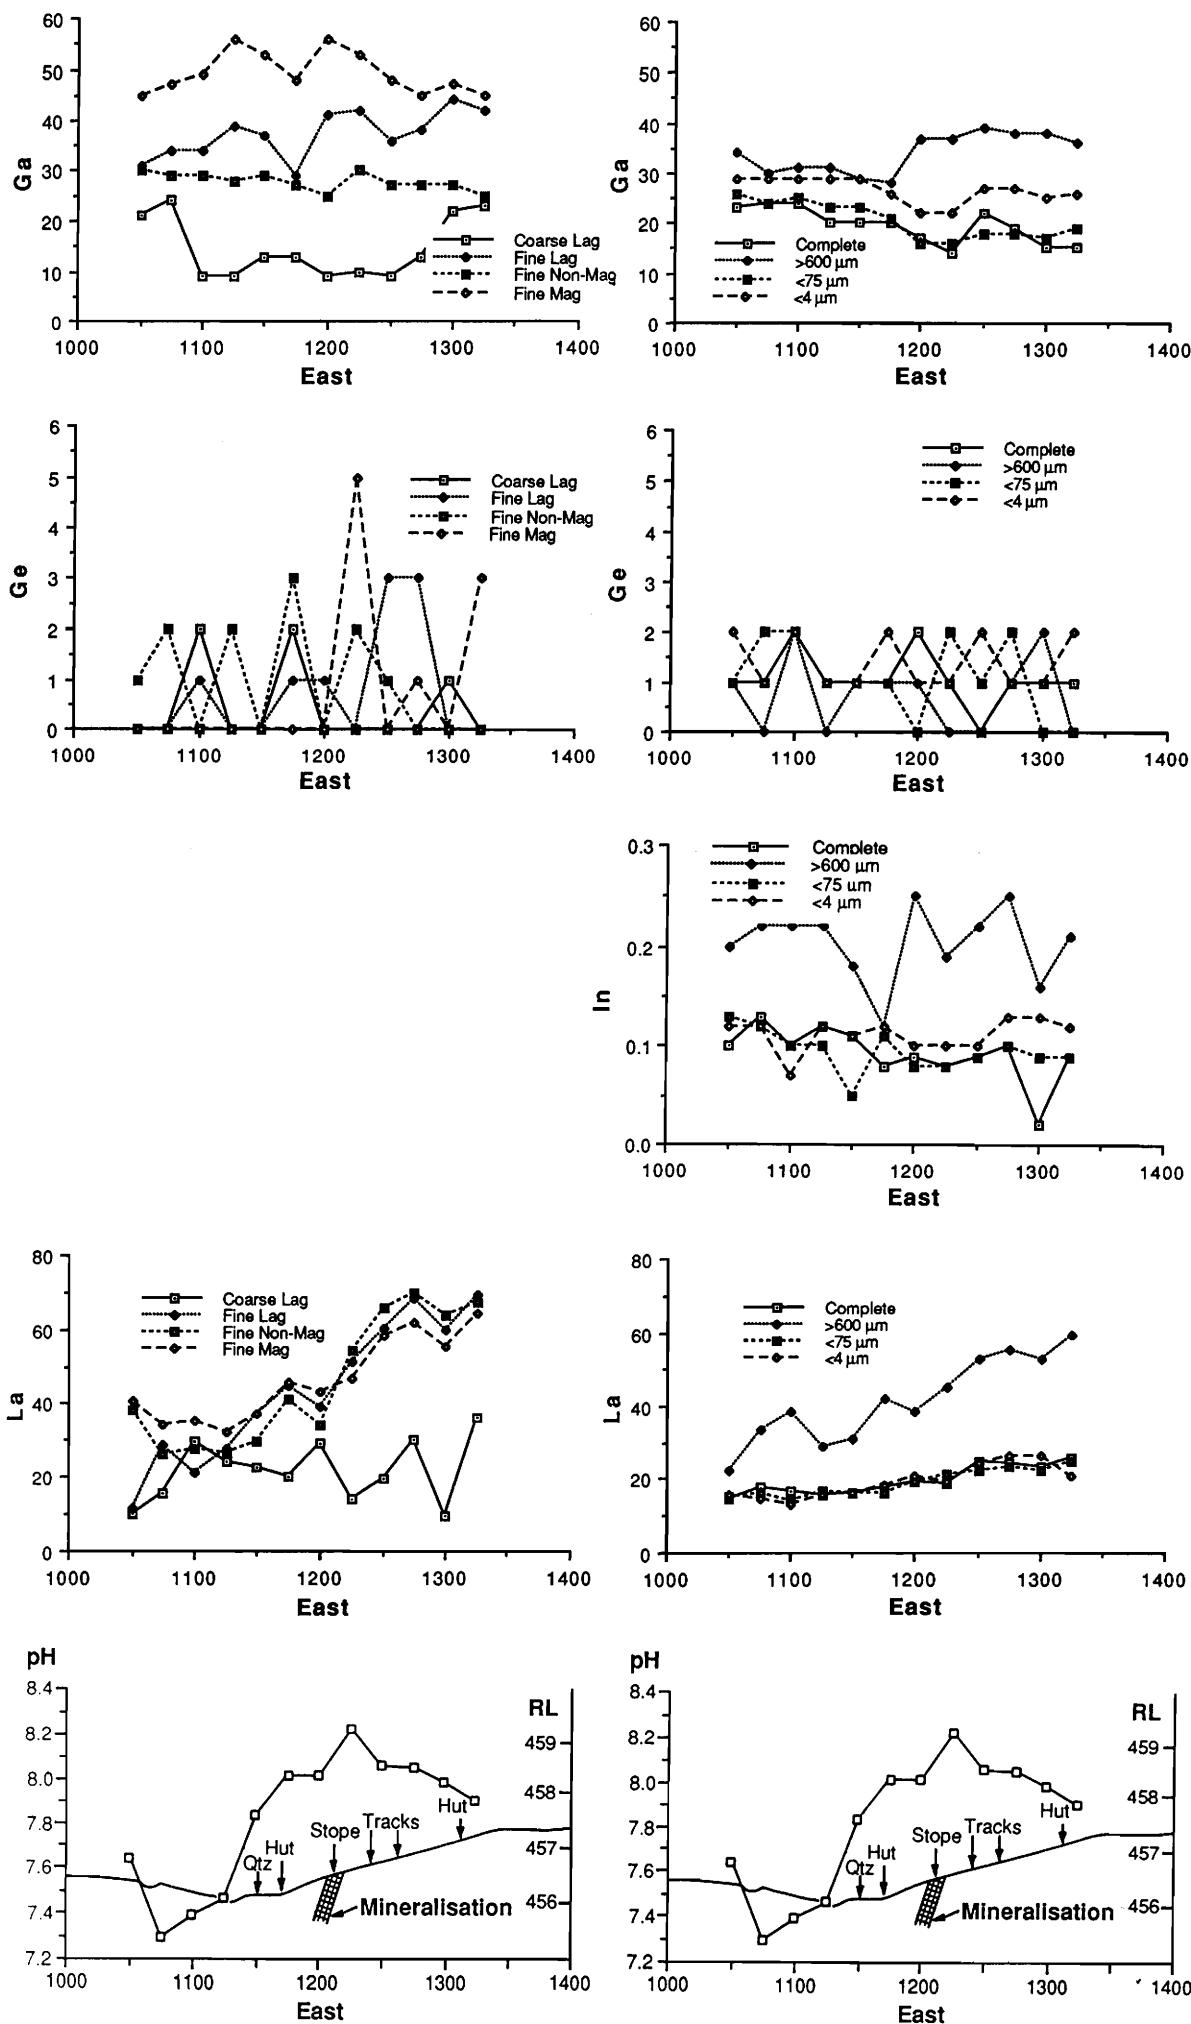

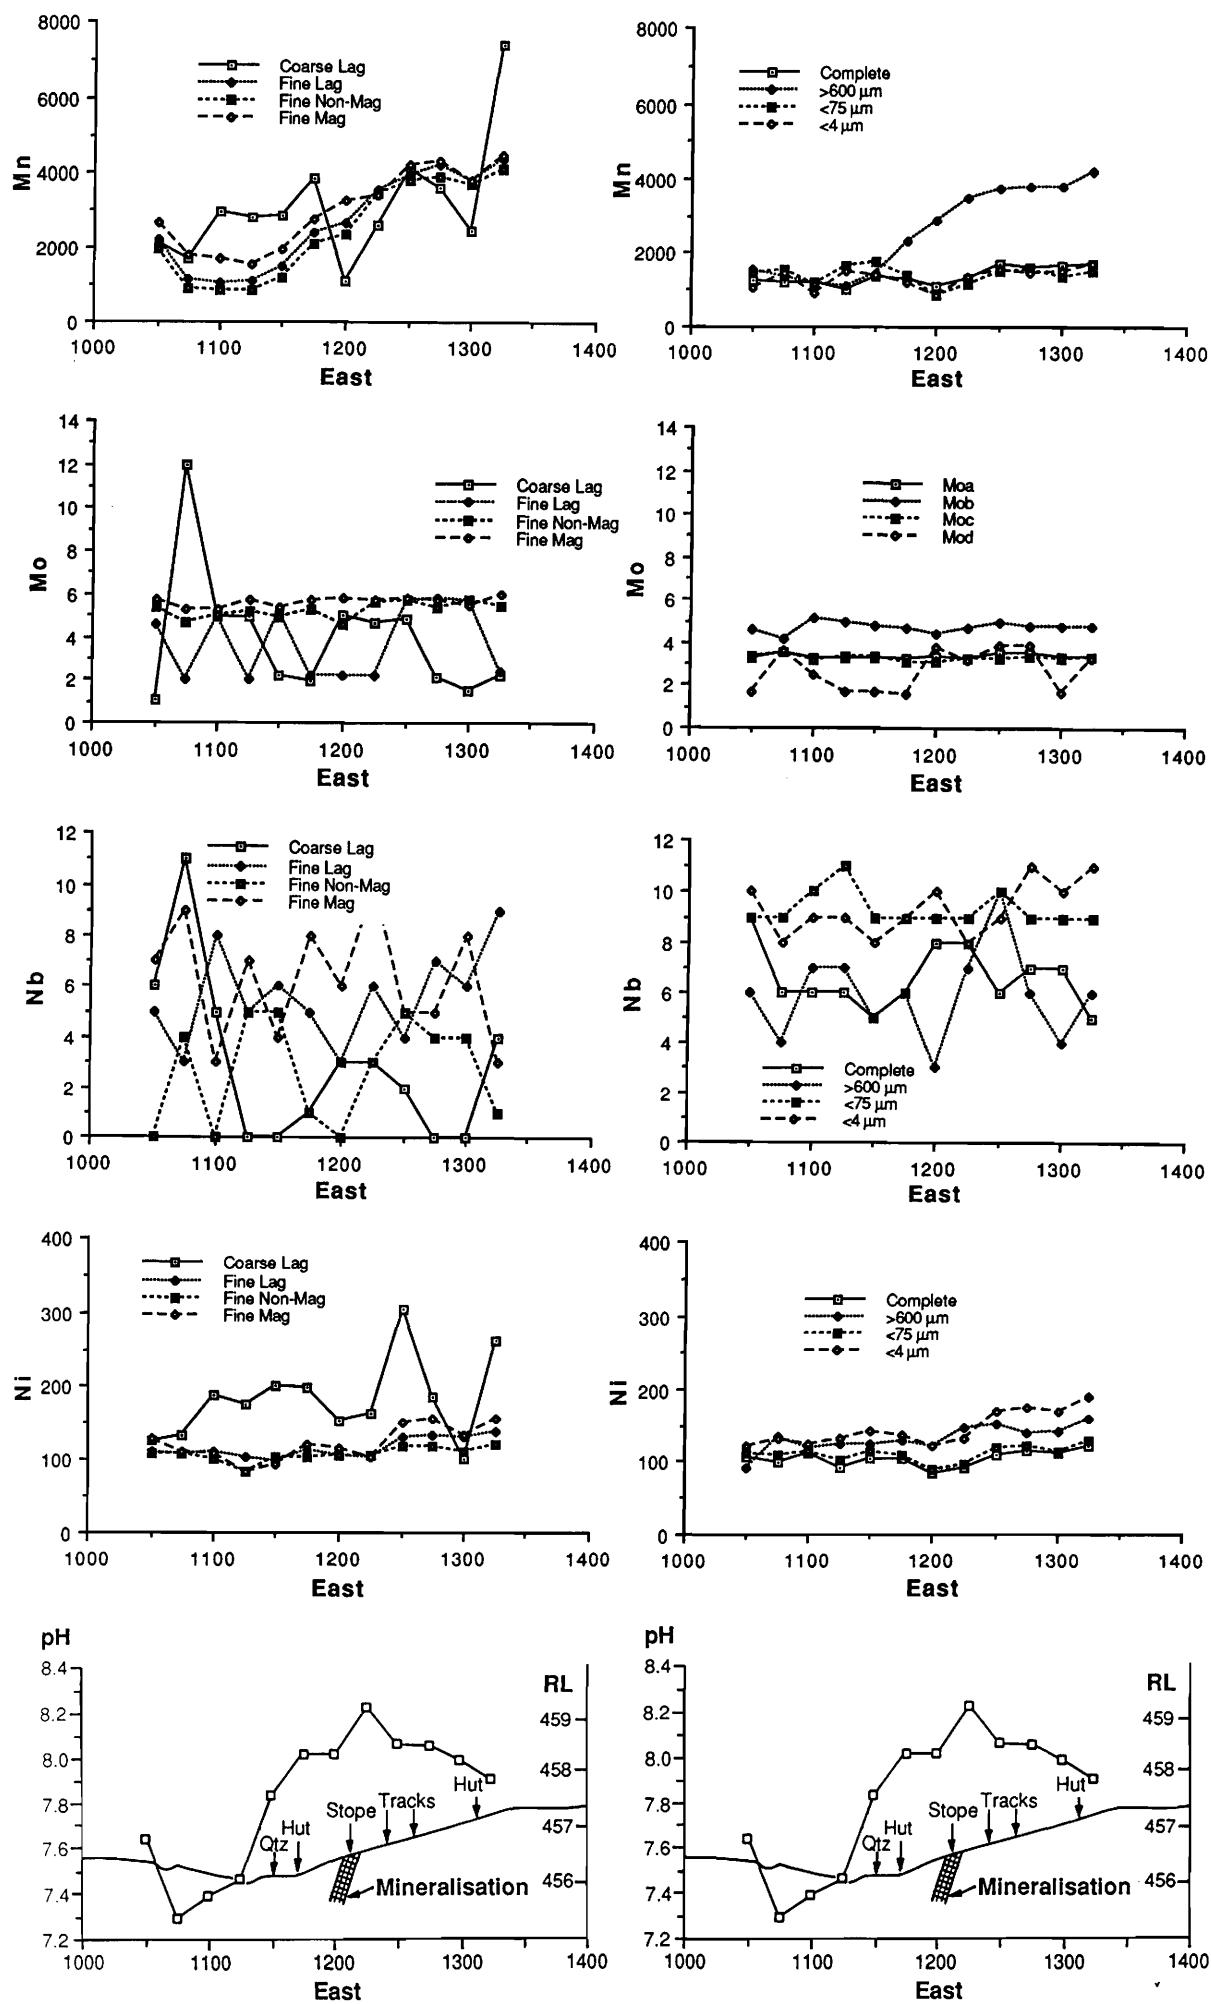

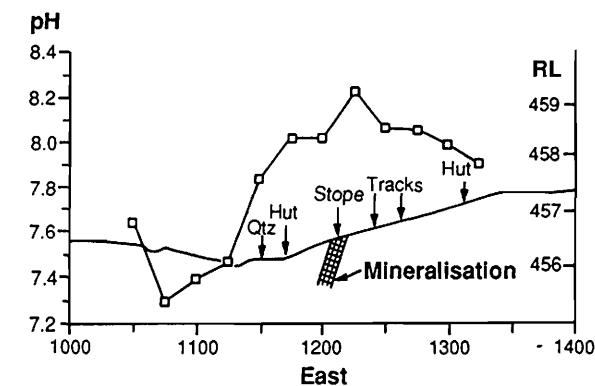

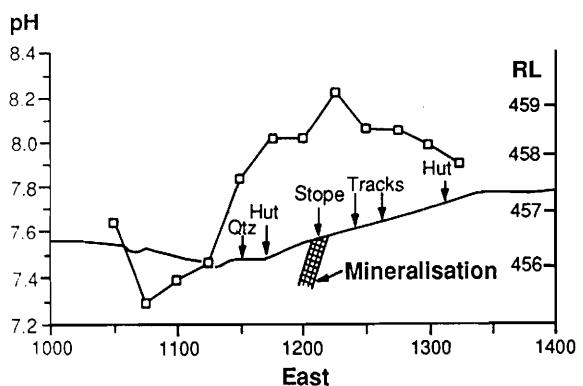

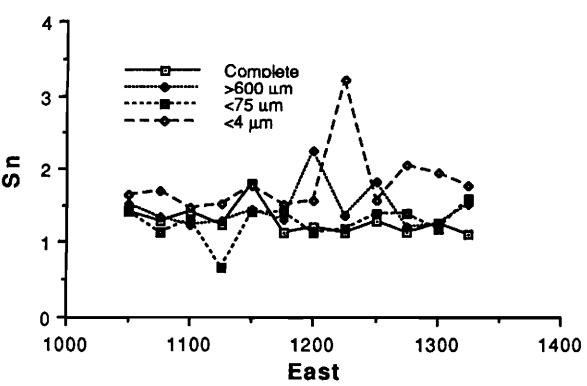

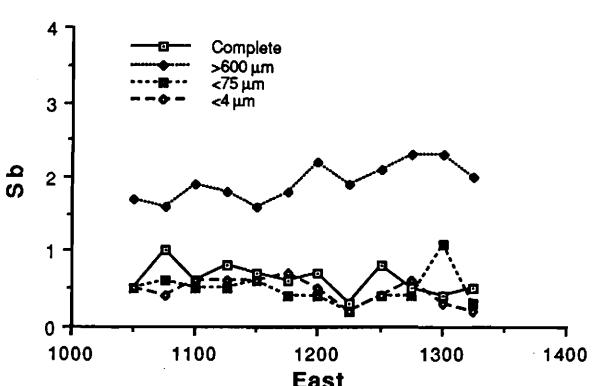

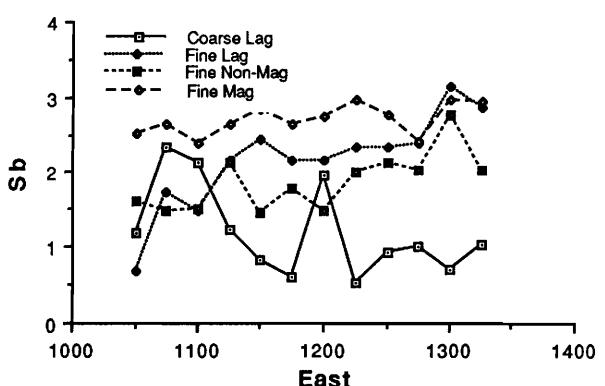

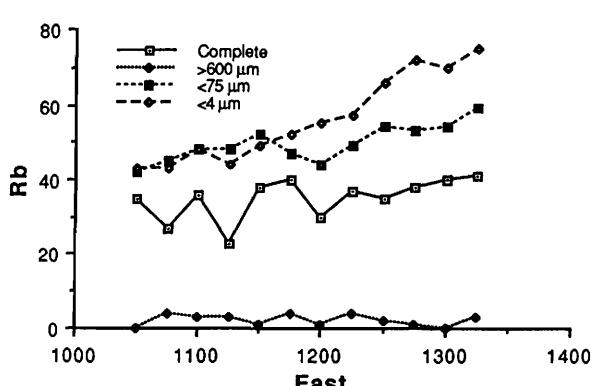

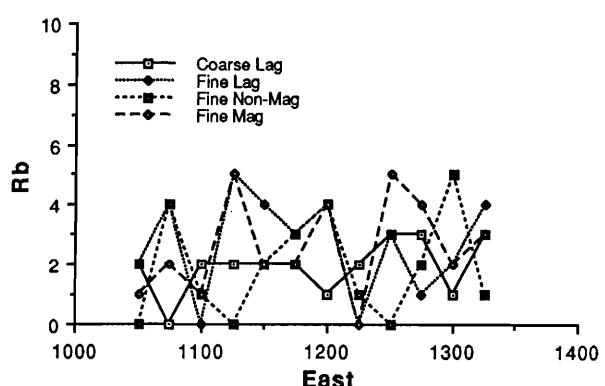

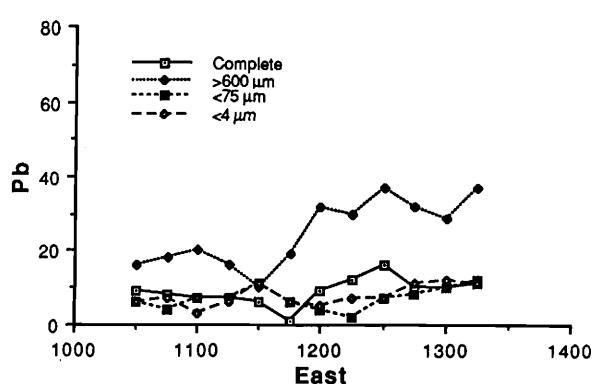

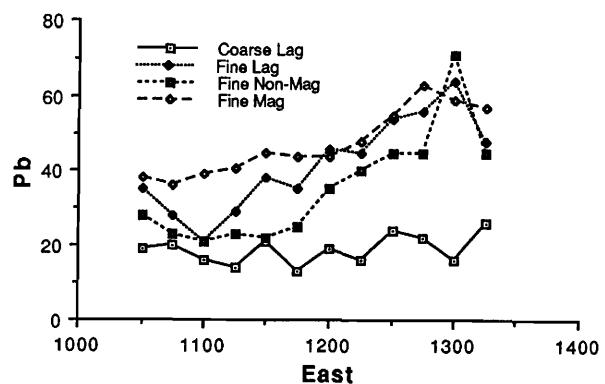

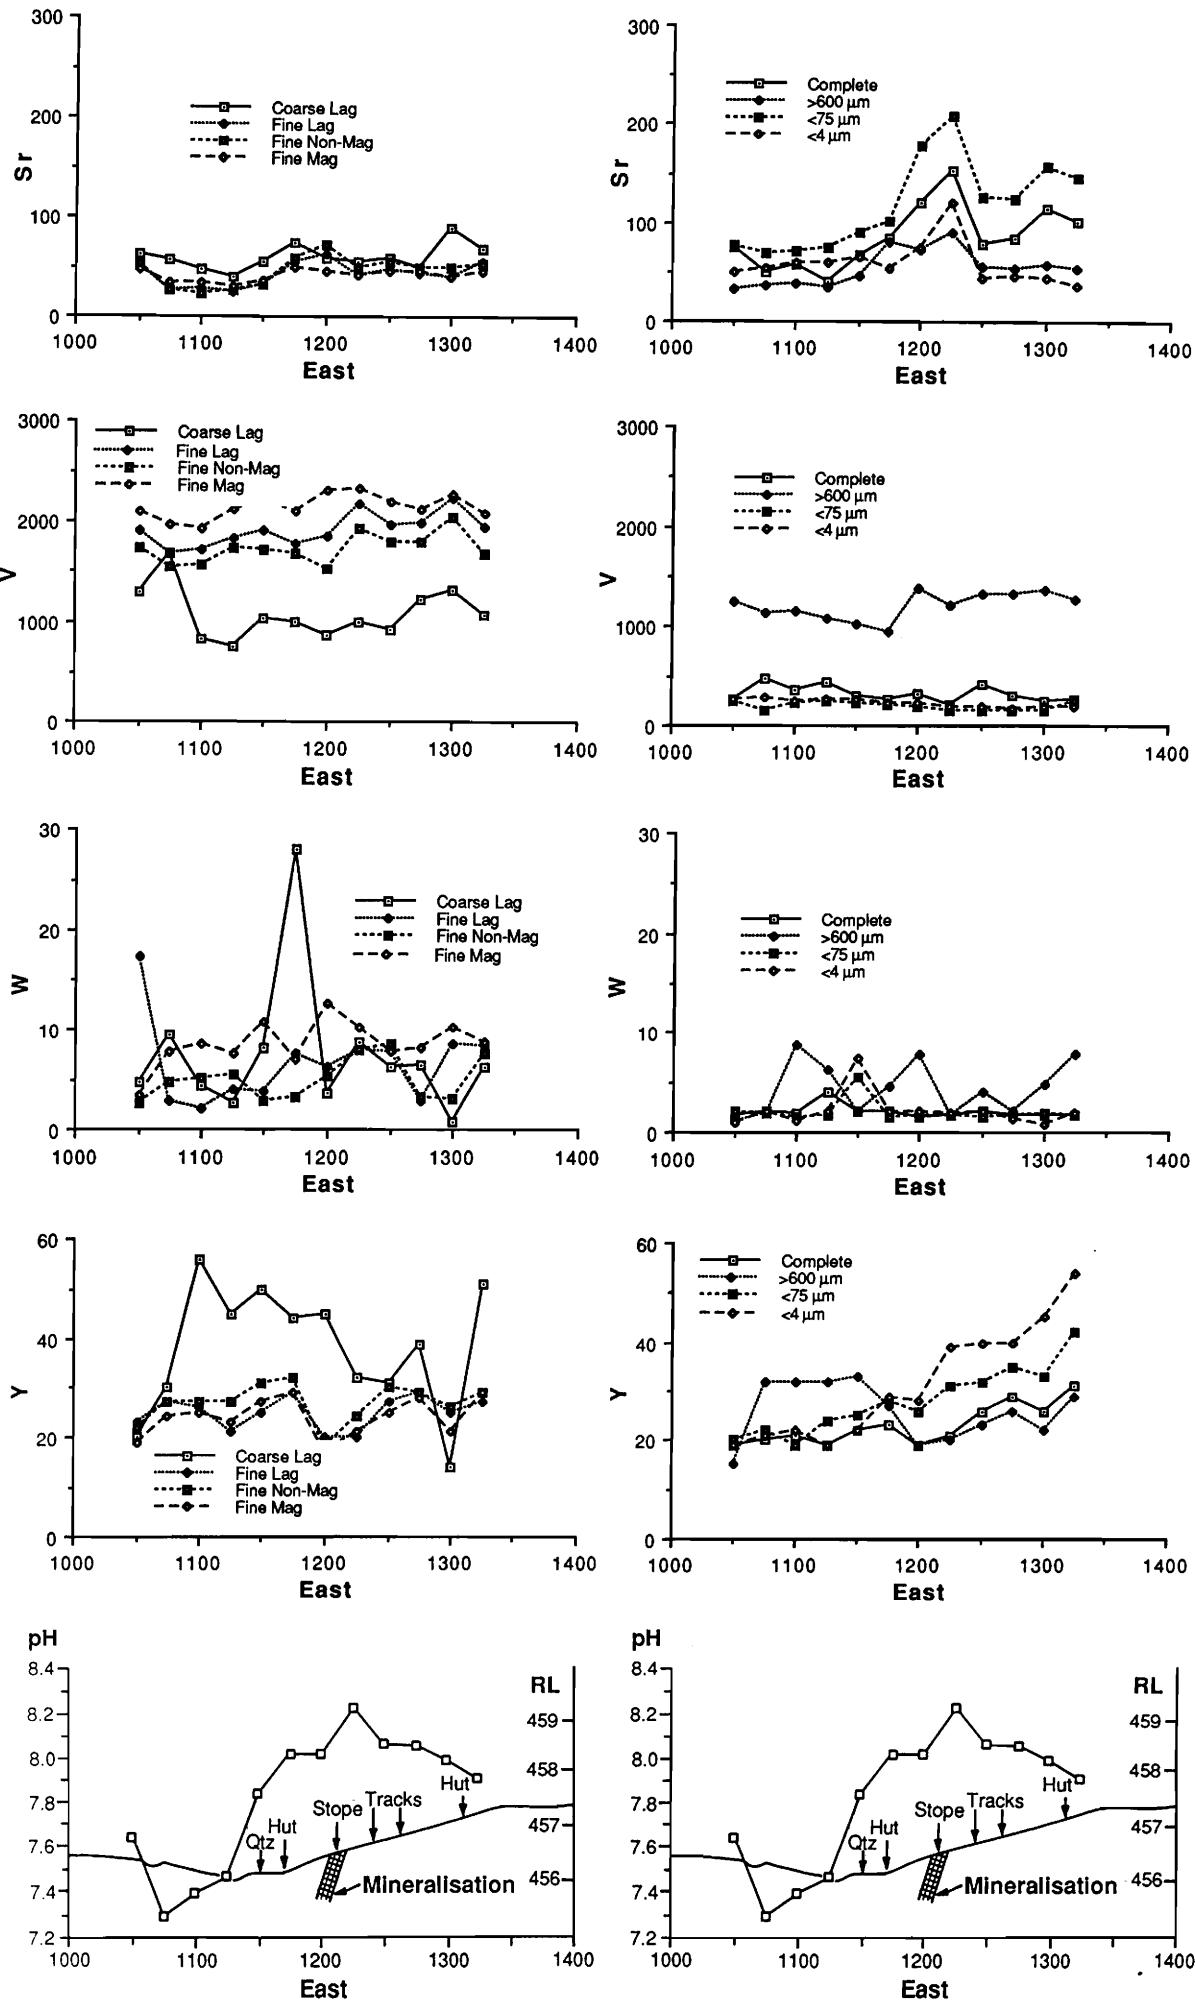

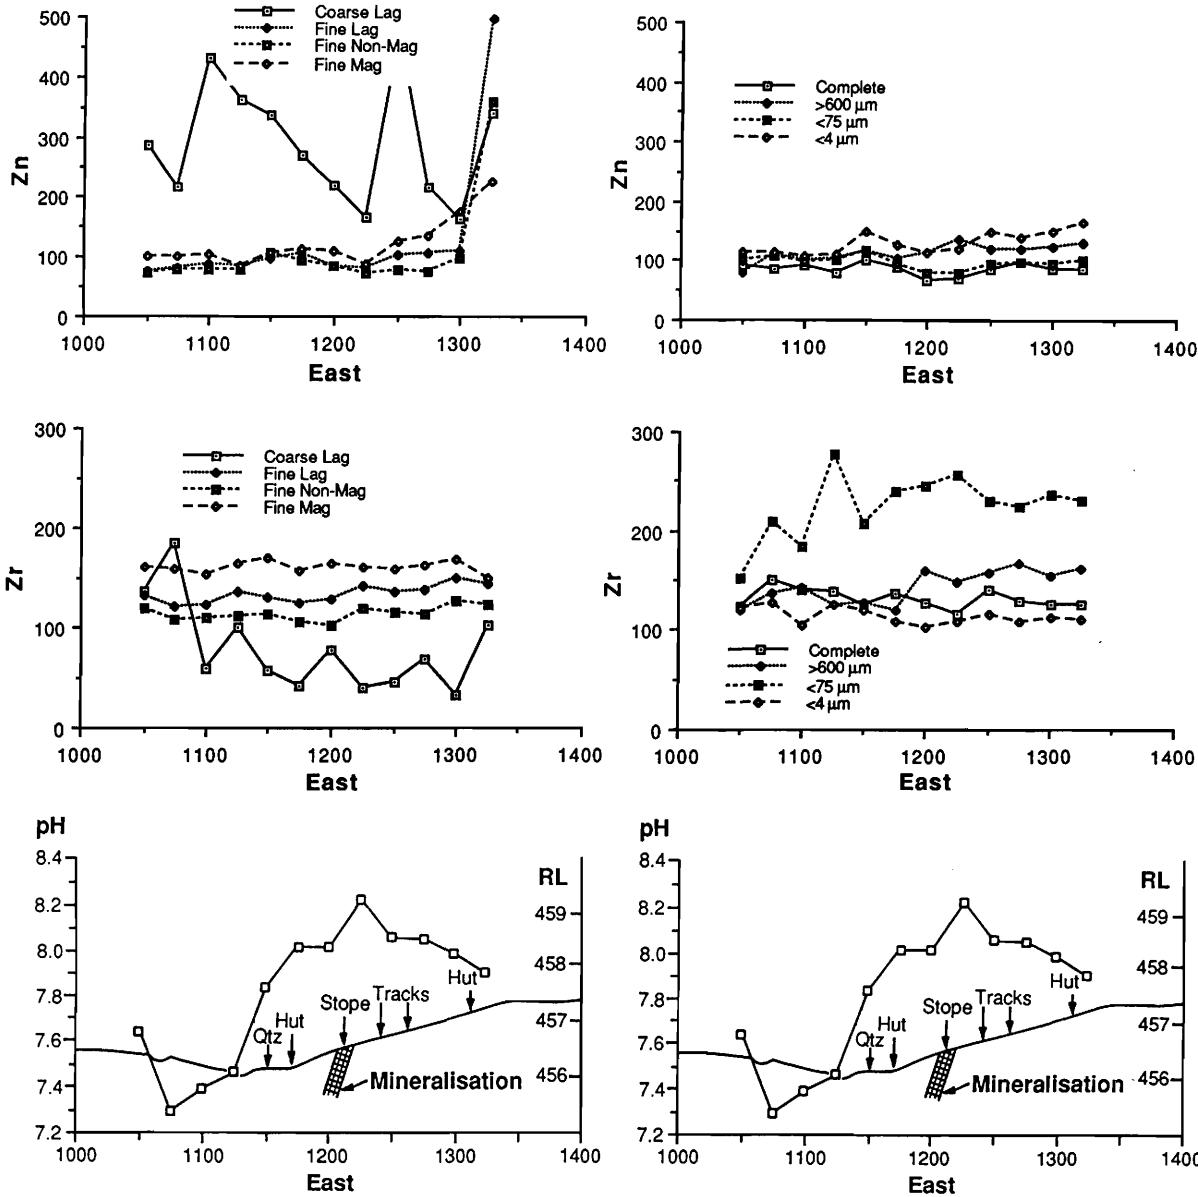

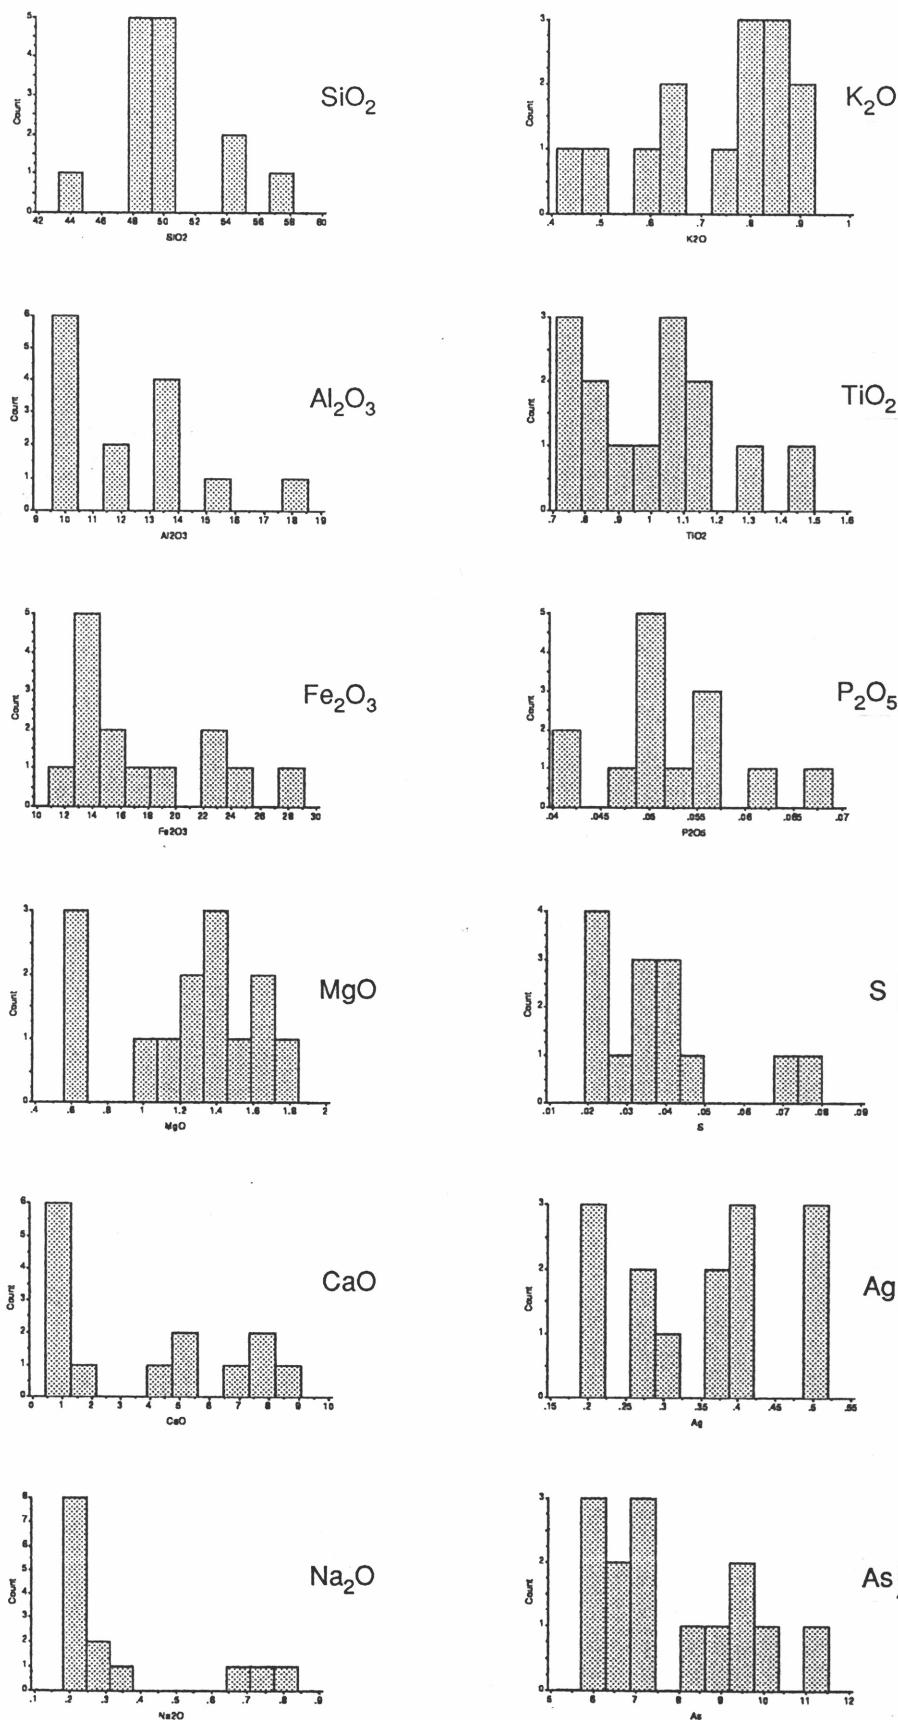

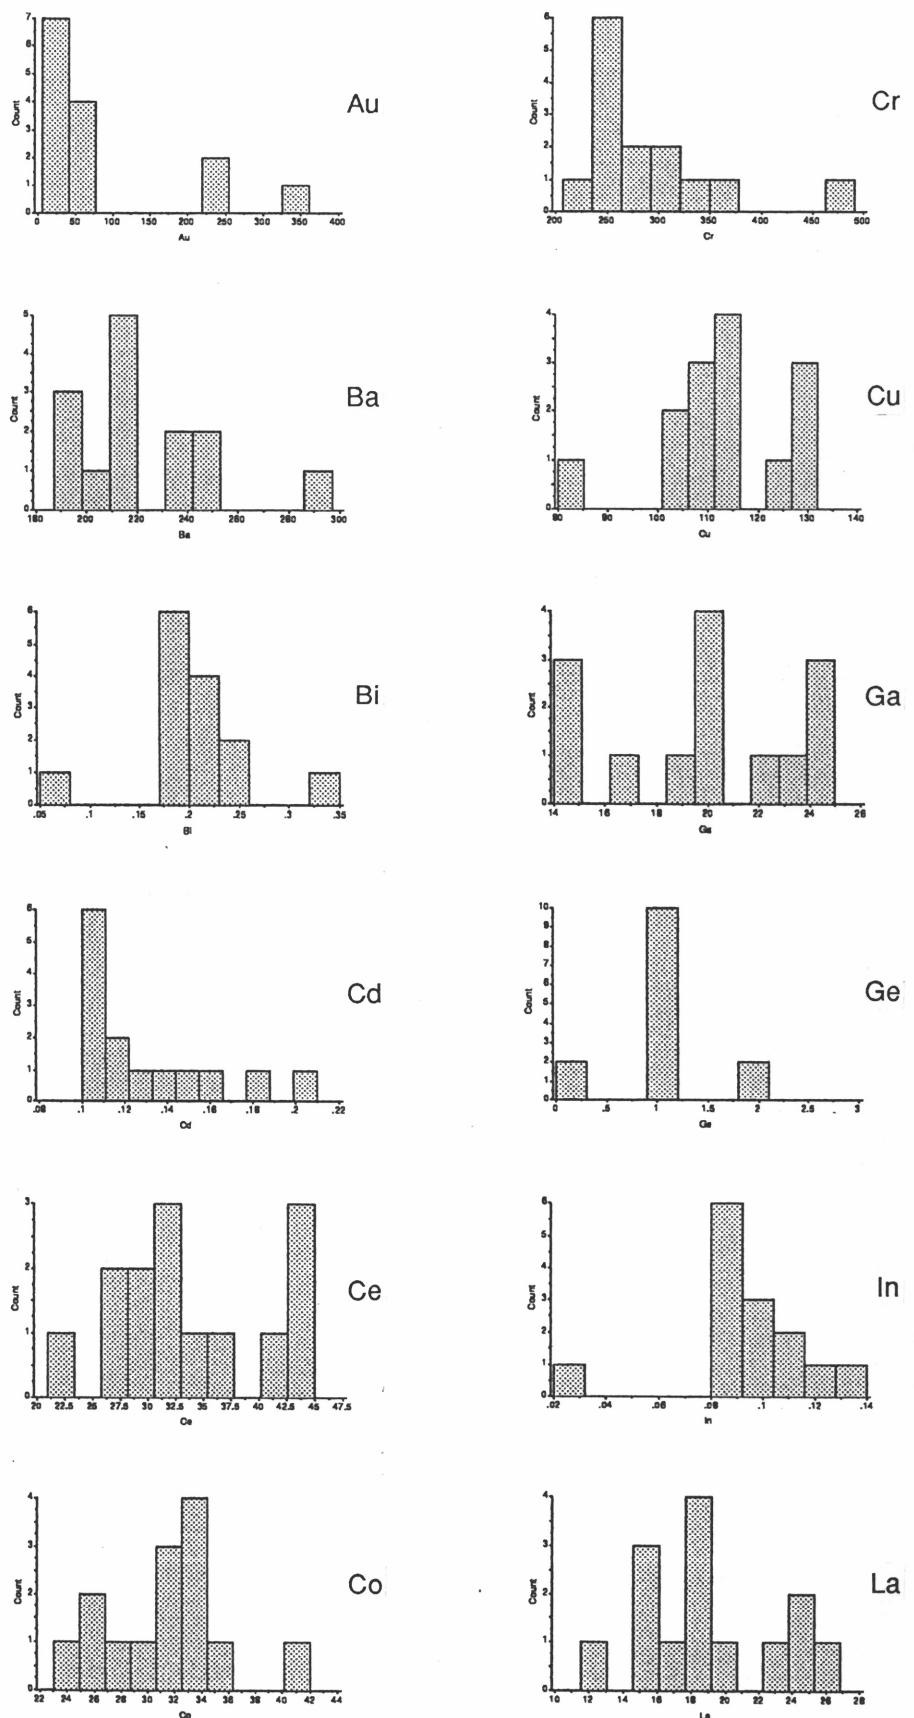

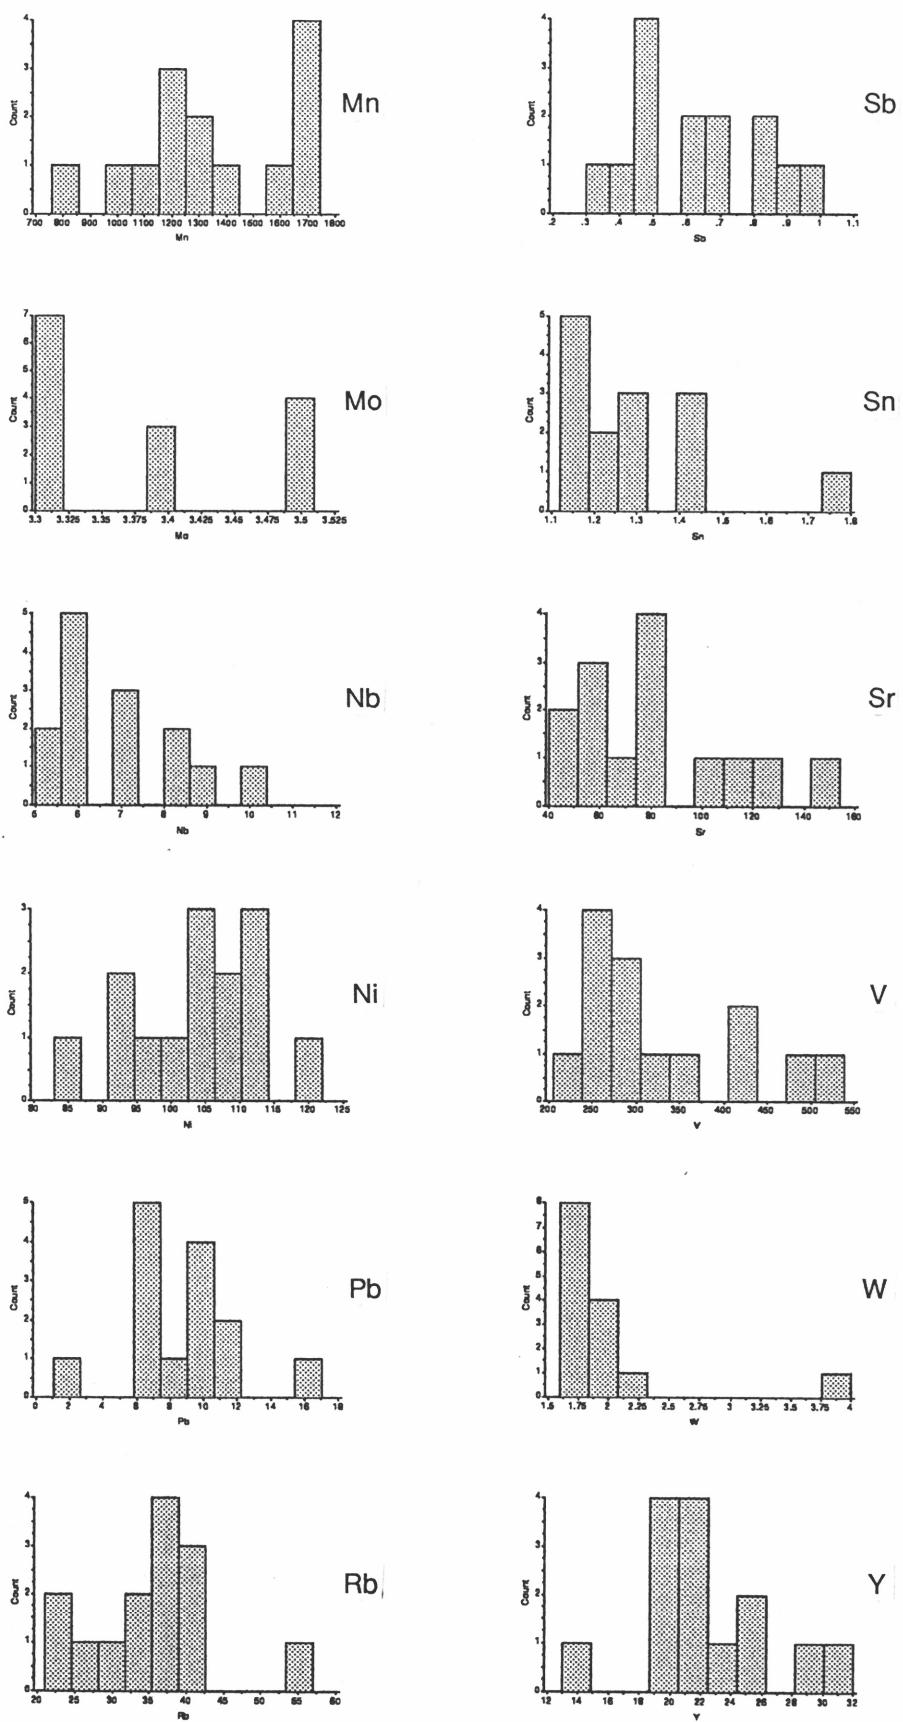

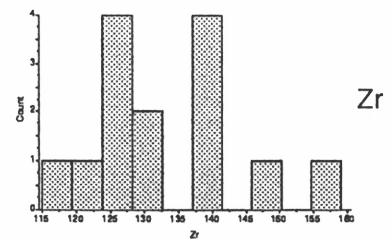

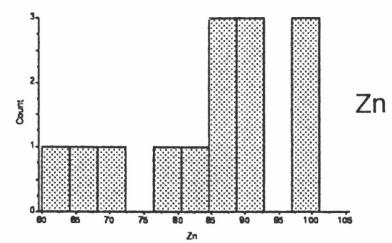

APPENDIX 4

Frequency Distributions - Complete Soil

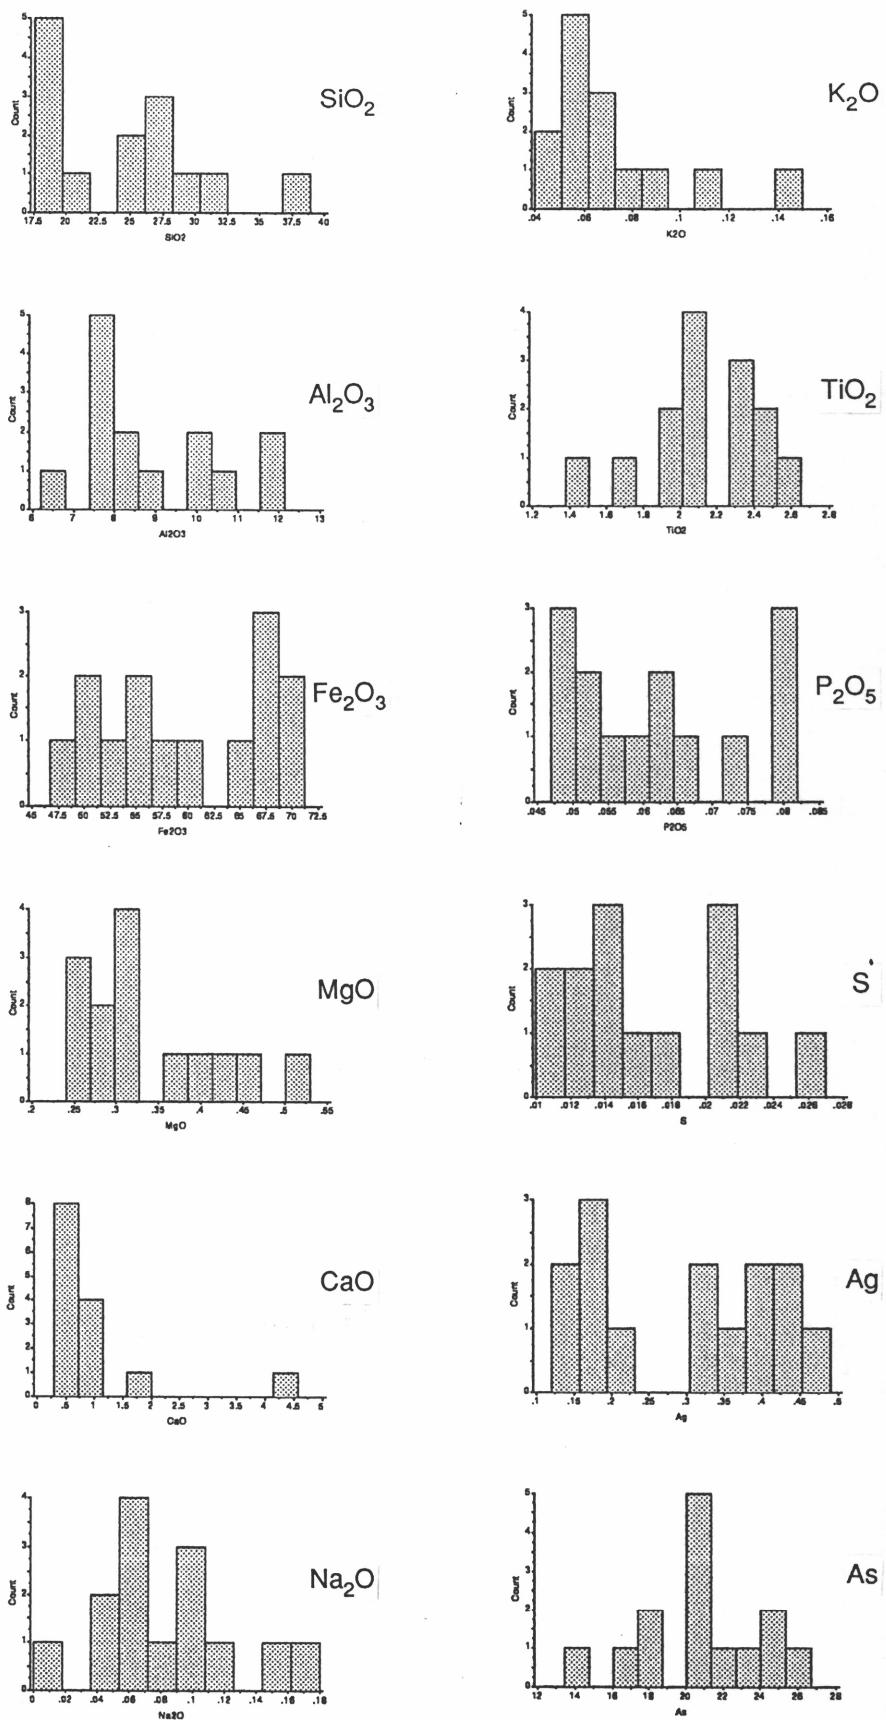

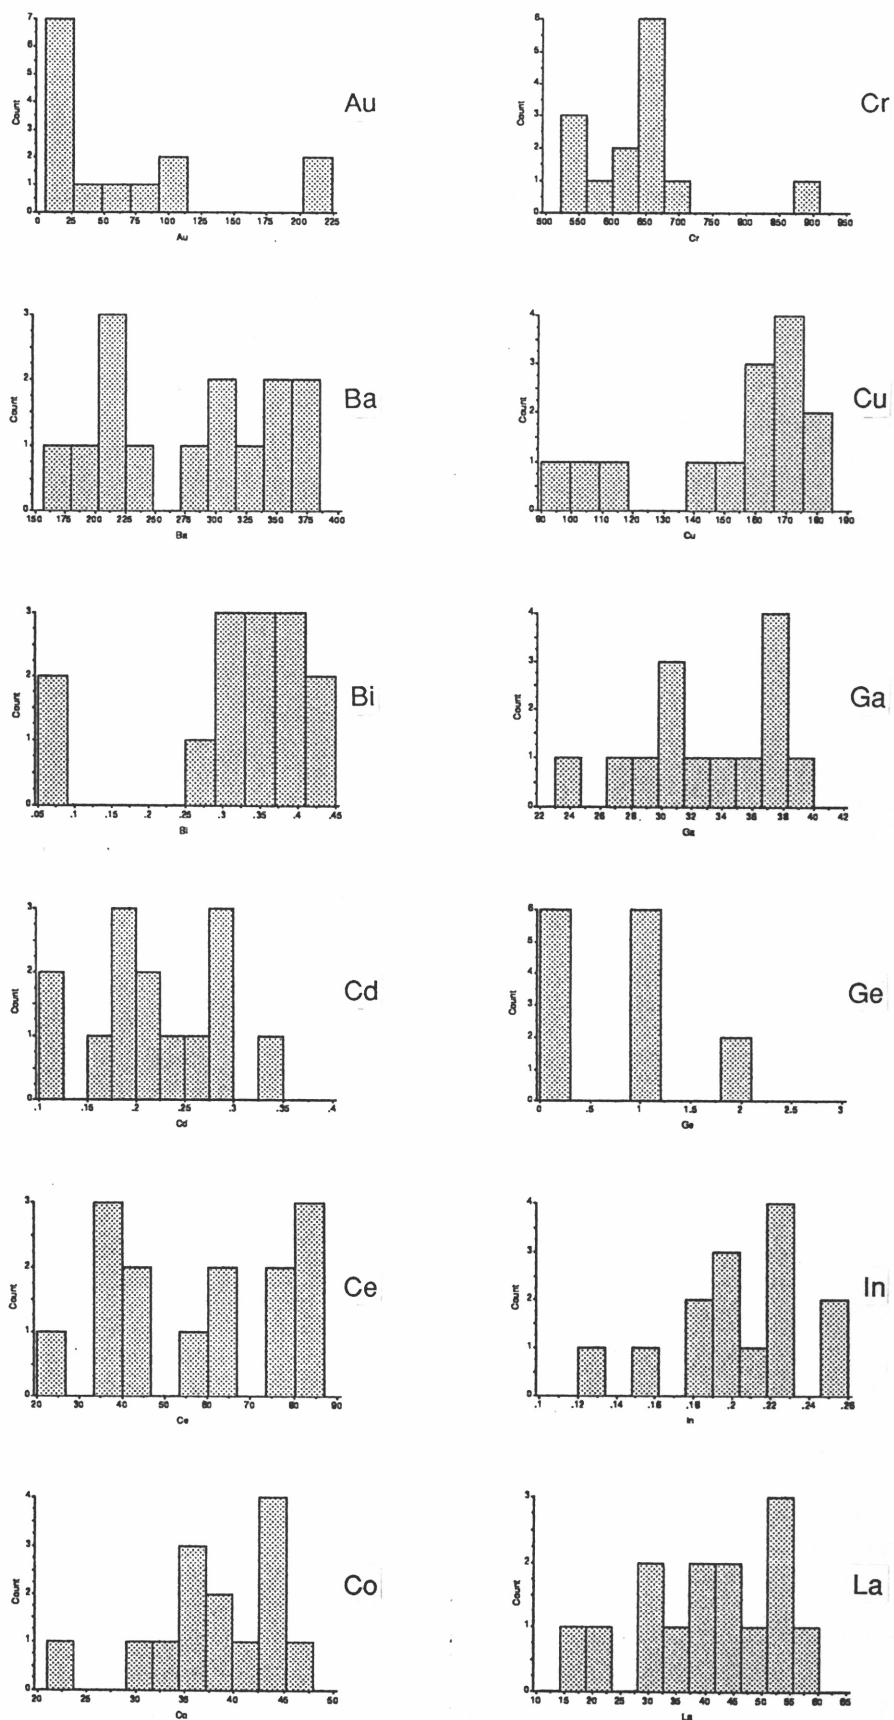

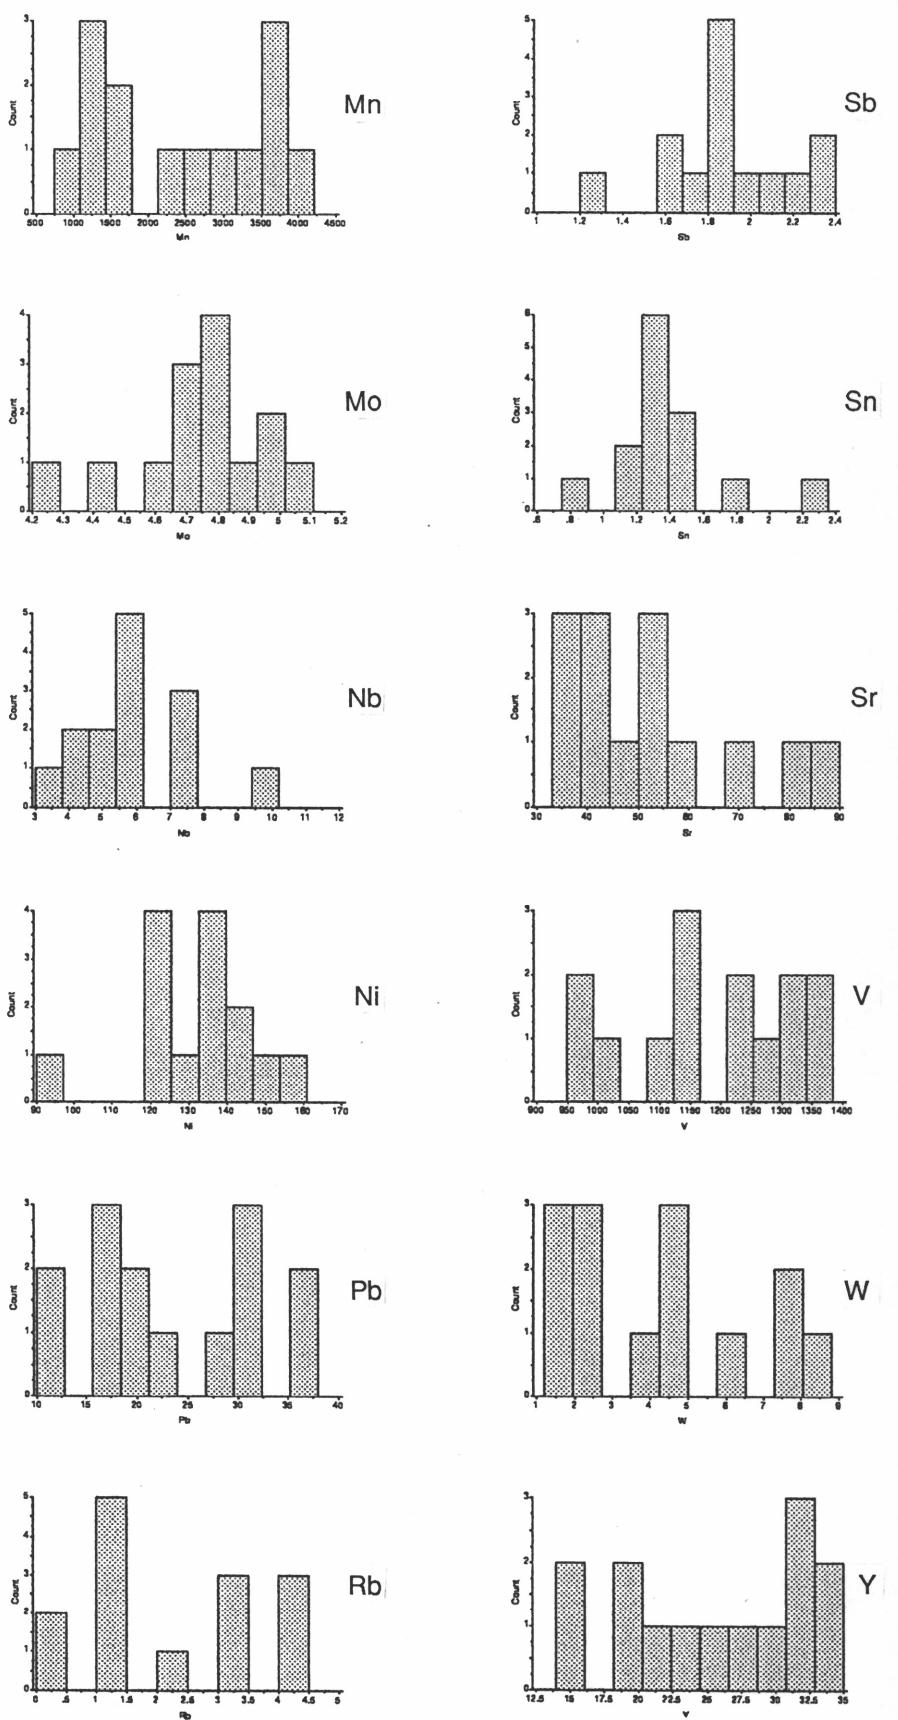

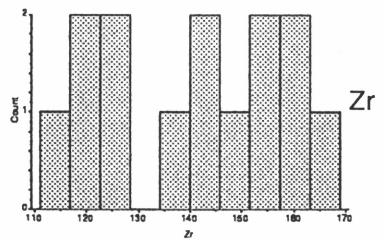

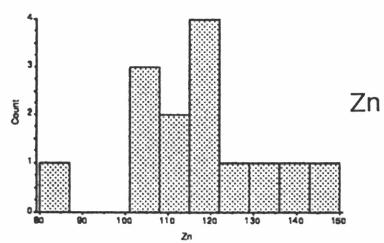

APPENDIX 5

Frequency Distributions - Soil > 600 μm

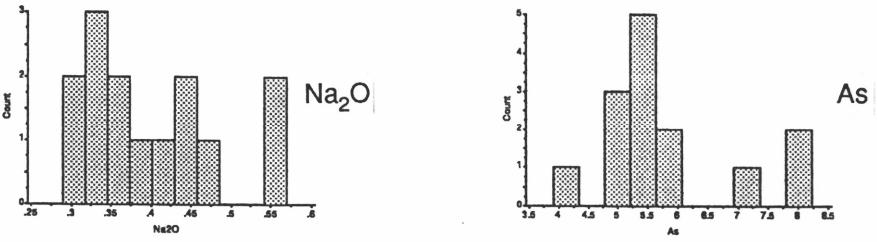

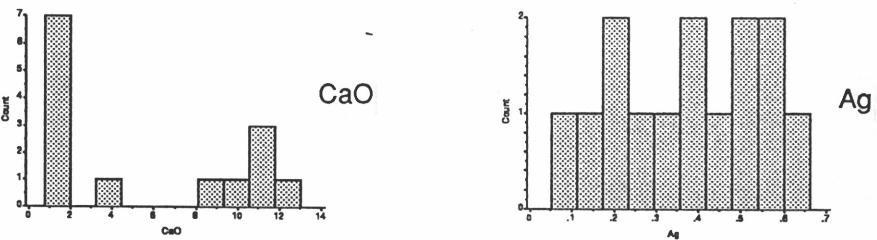

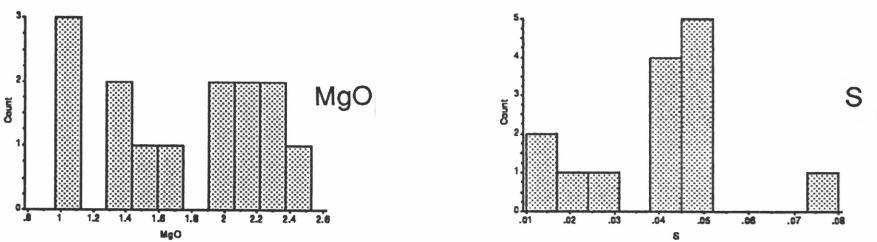

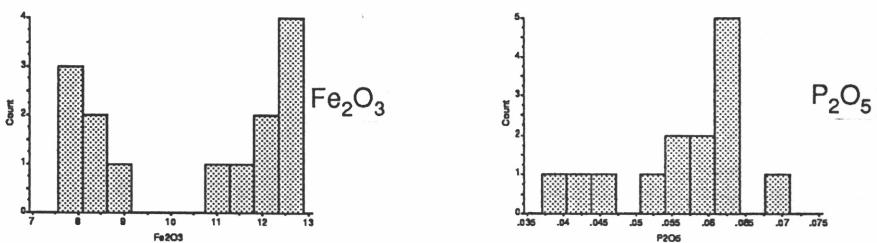

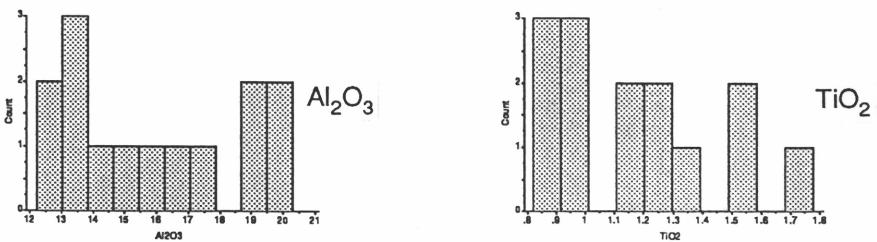

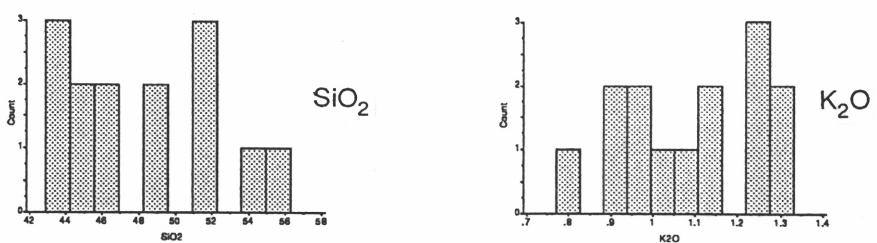

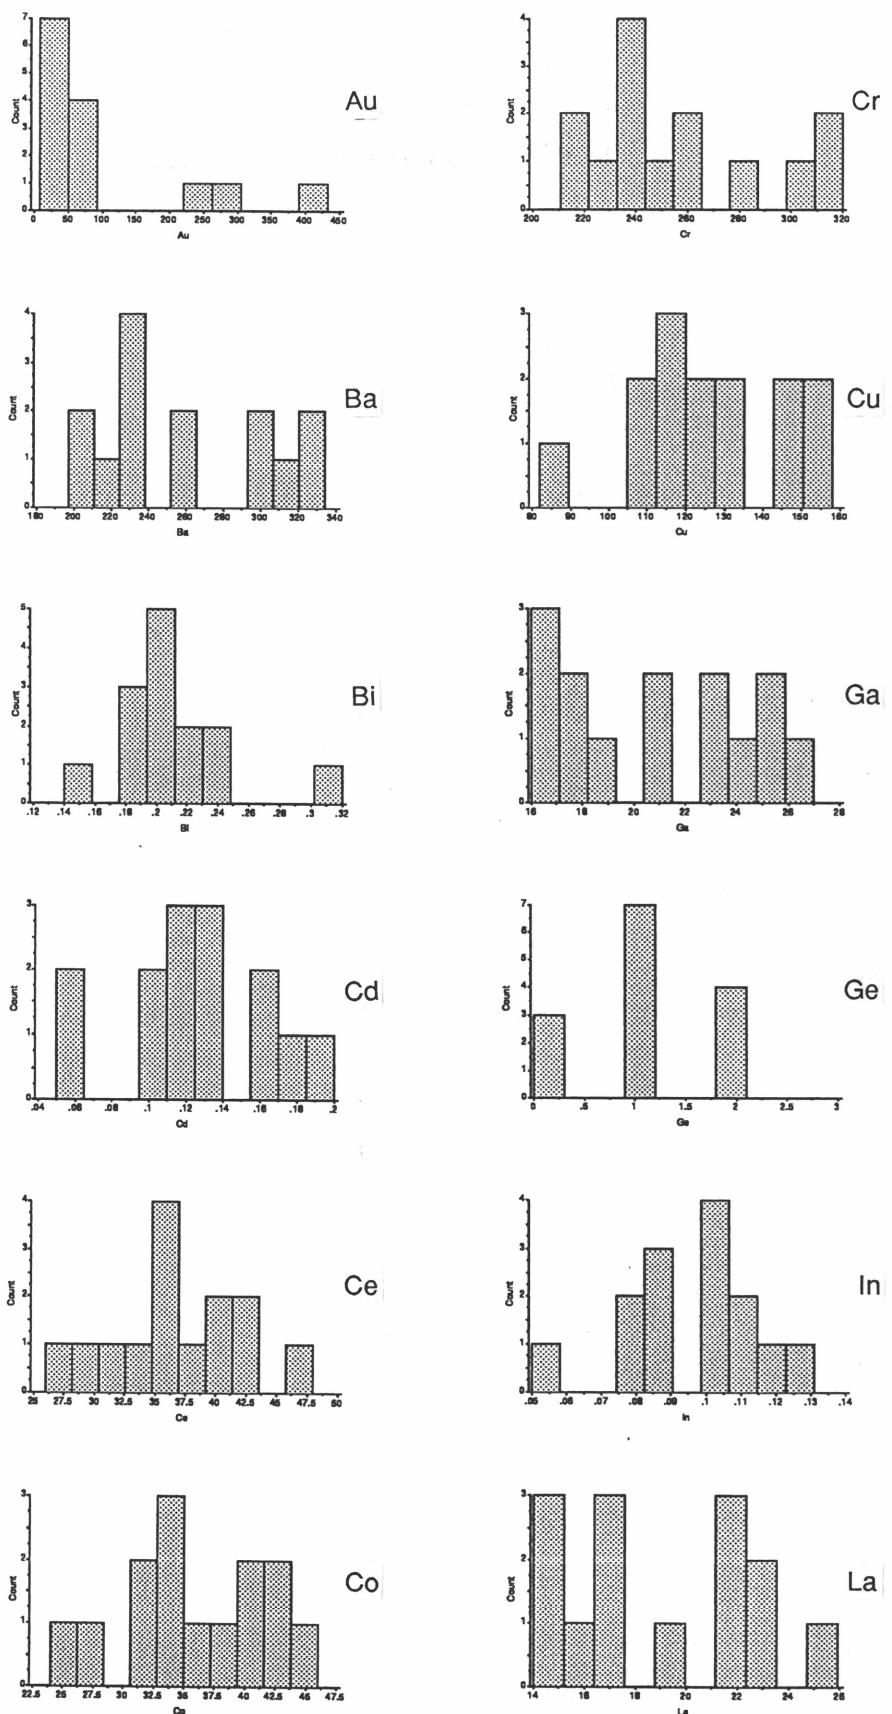

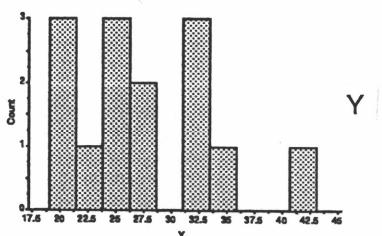

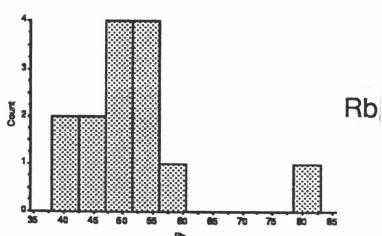

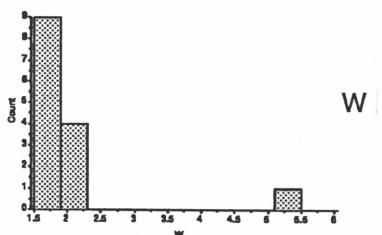

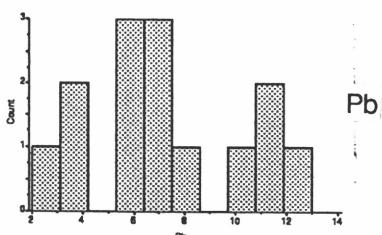

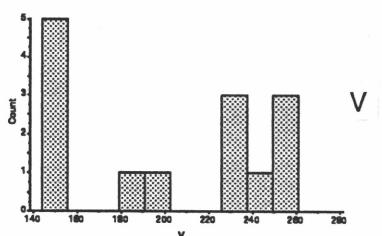

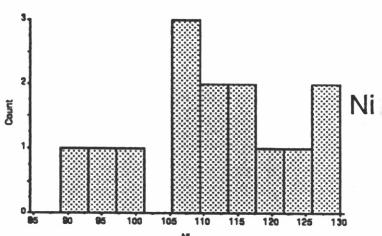

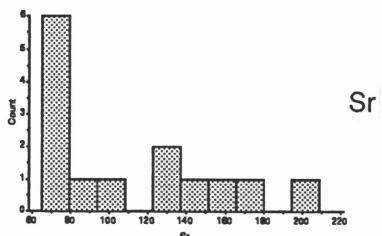

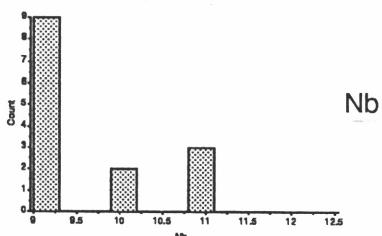

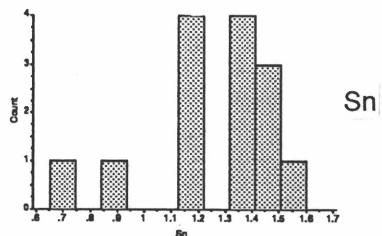

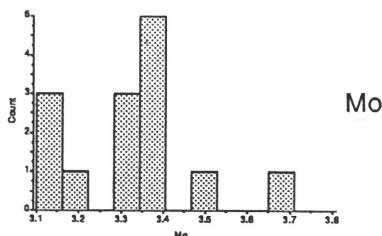

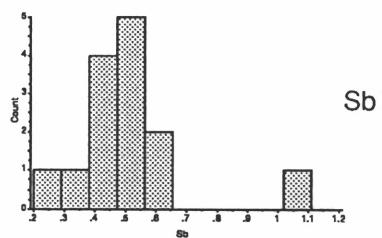

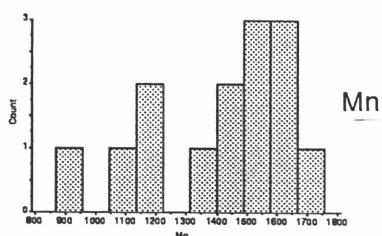

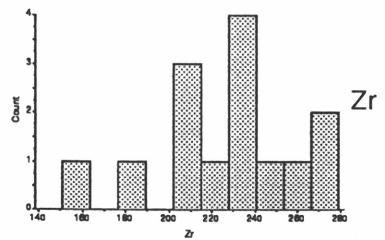

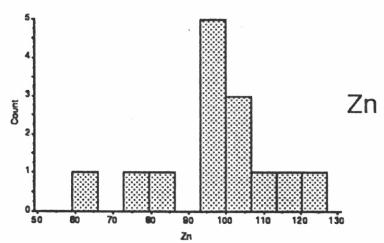

APPENDIX 6

Frequency Distributions - Soil <75 μm

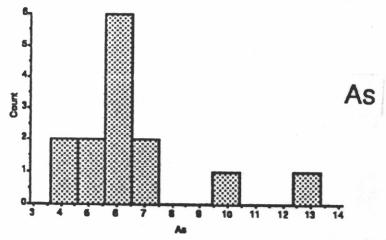

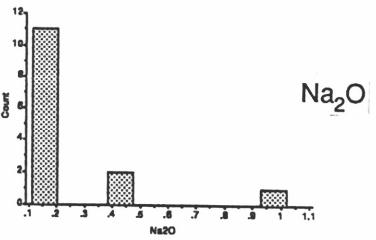

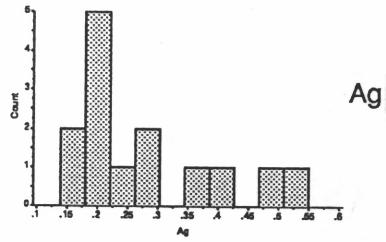

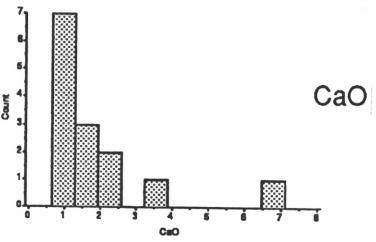

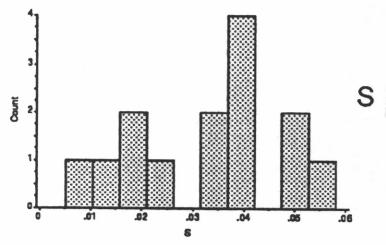

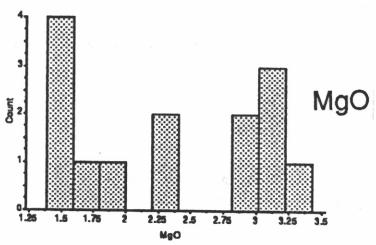

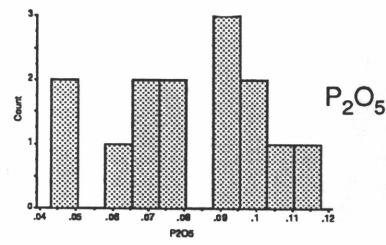

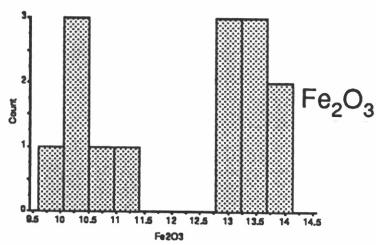

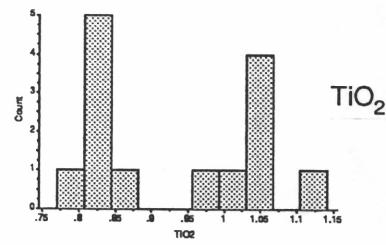

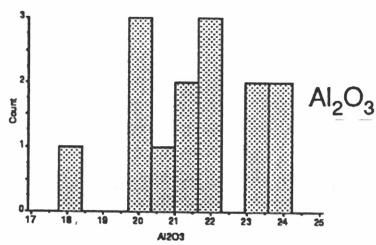

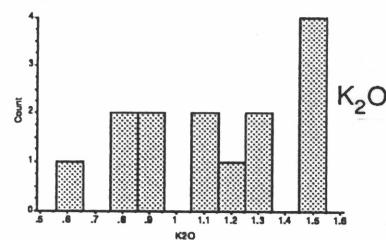

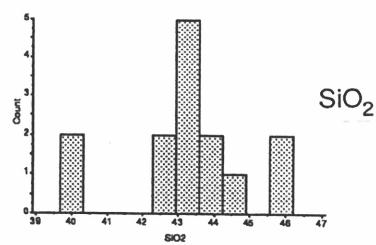

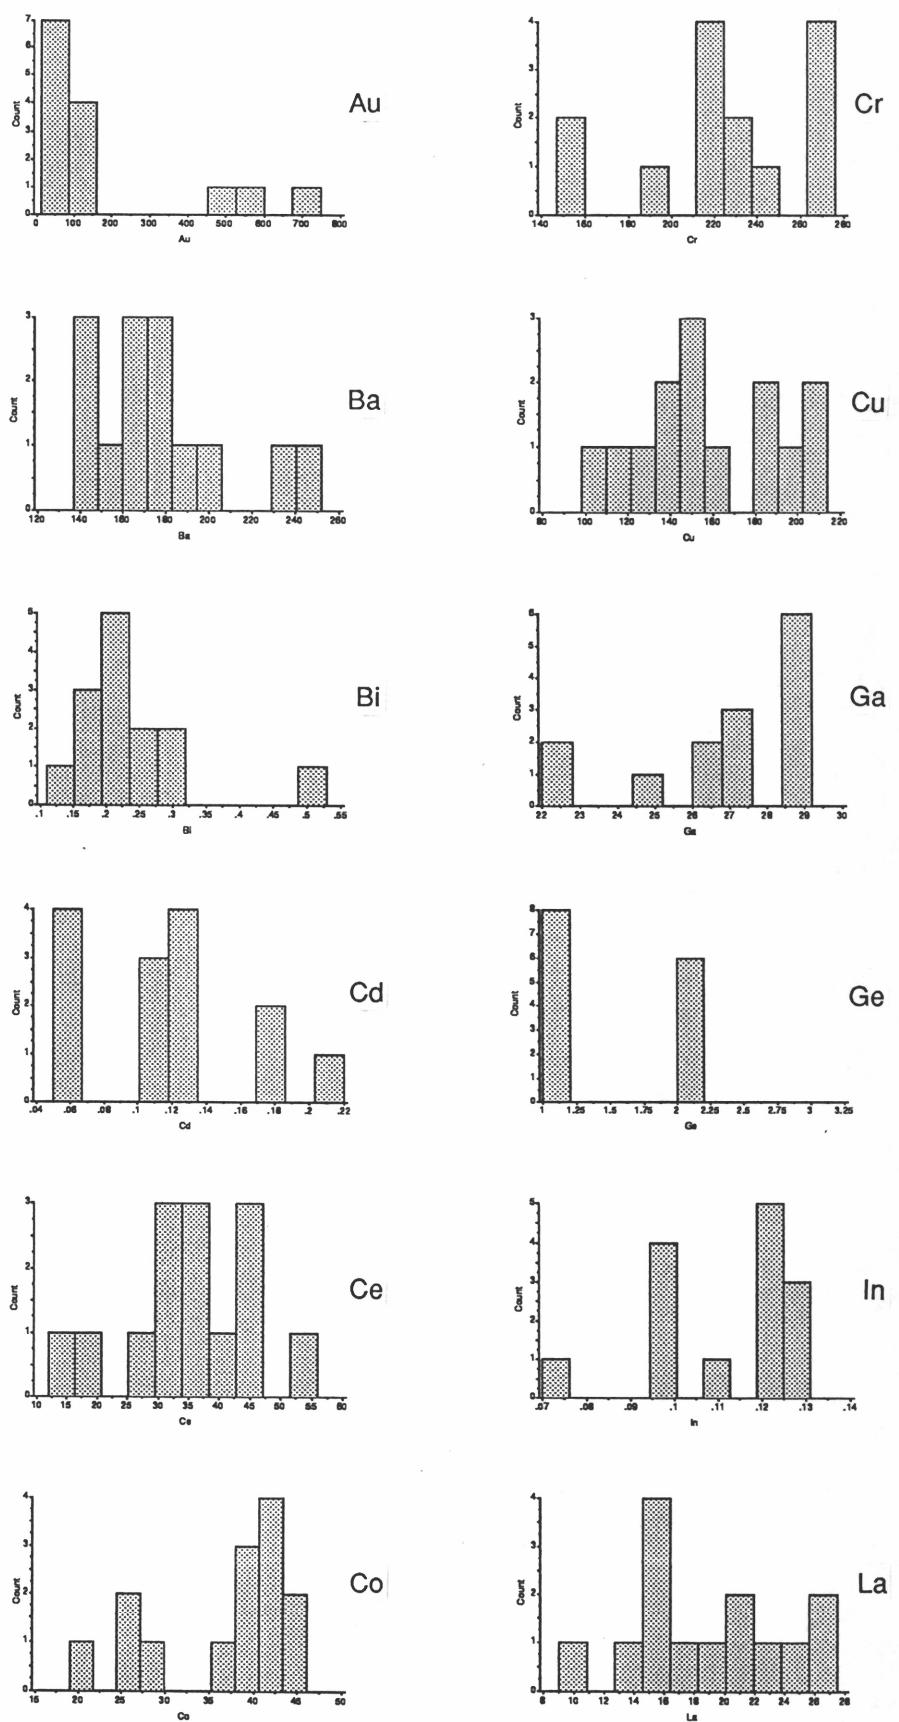

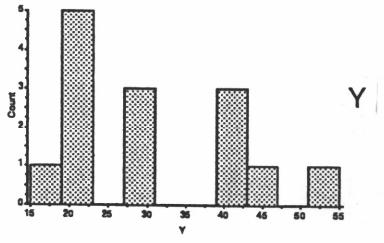

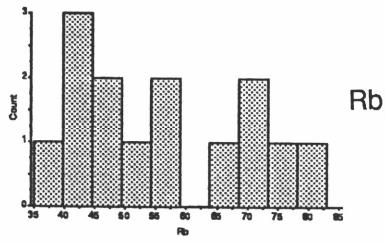

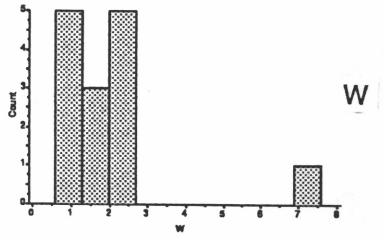

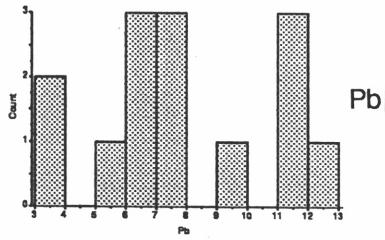

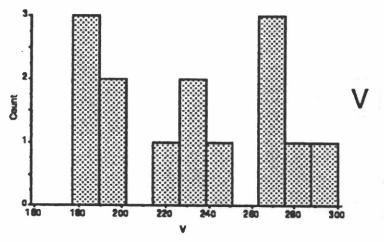

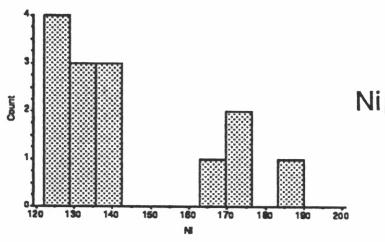

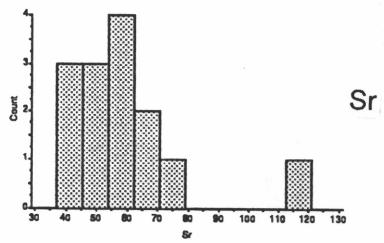

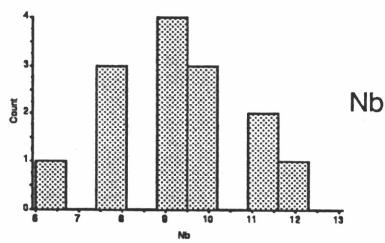

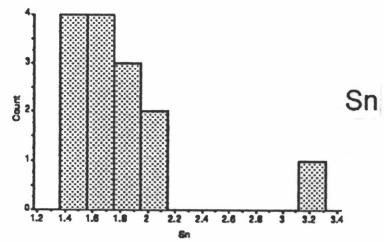

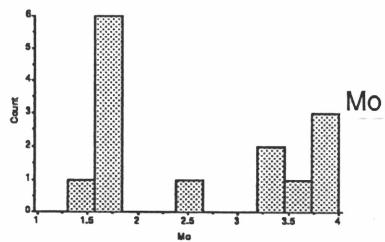

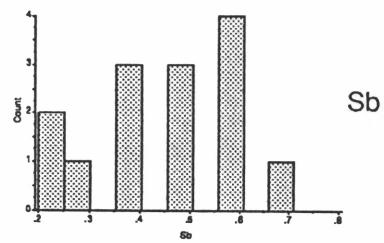

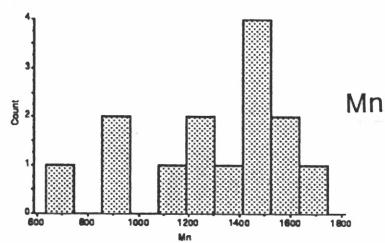

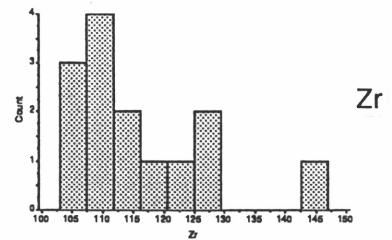

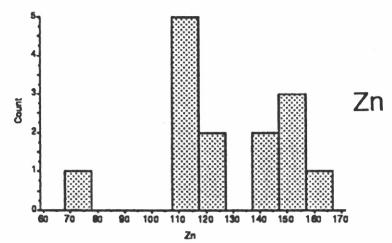

APPENDIX 7

Frequency Distribution - Soil <4 μm

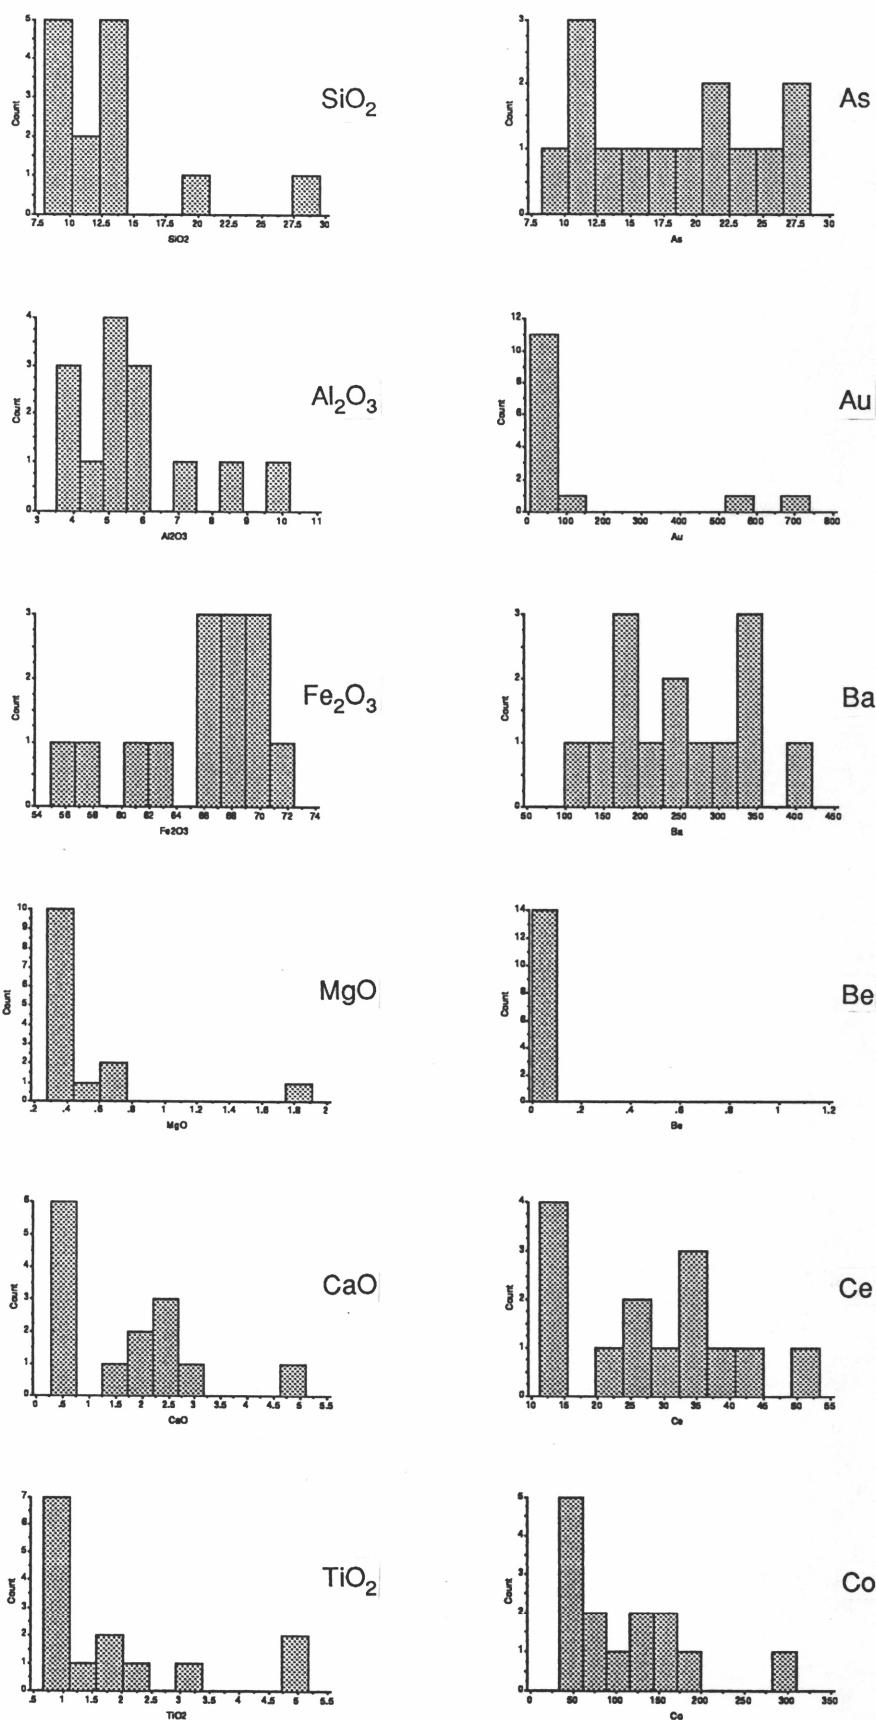

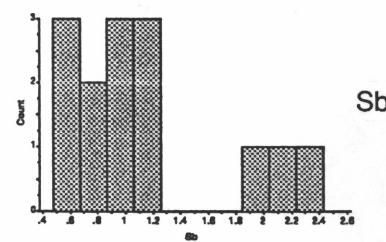

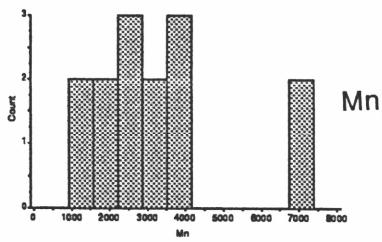

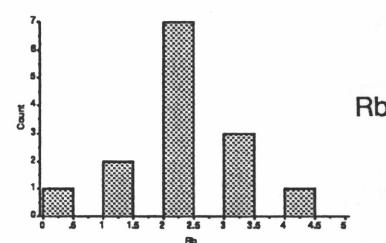

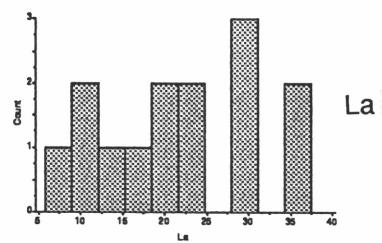

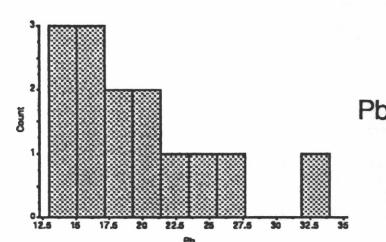

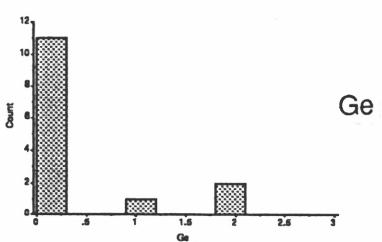

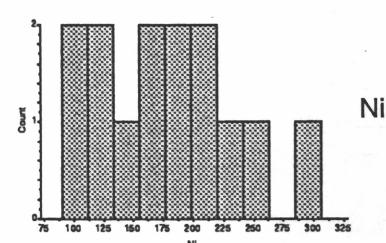

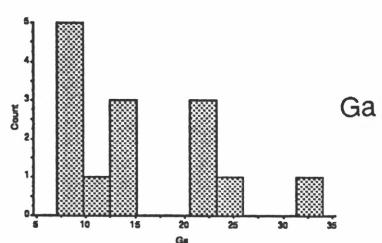

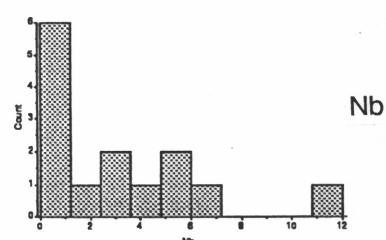

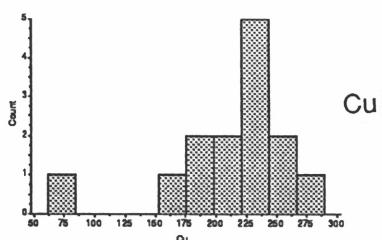

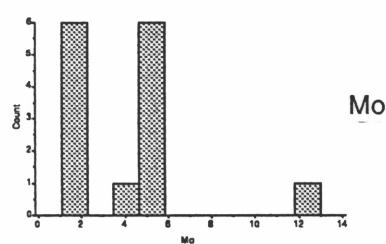

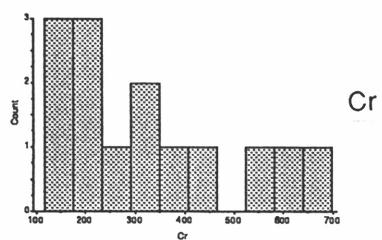

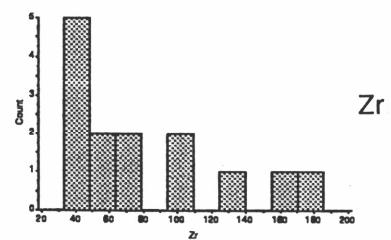

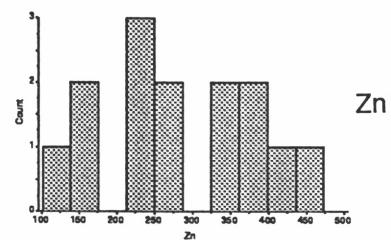

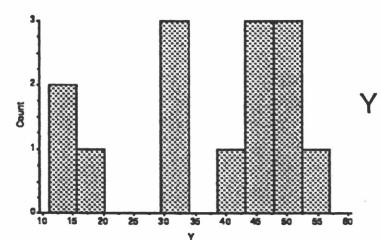

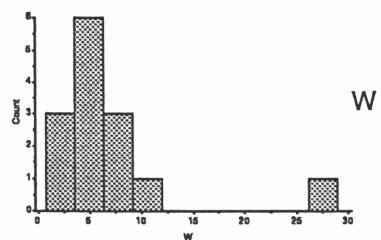

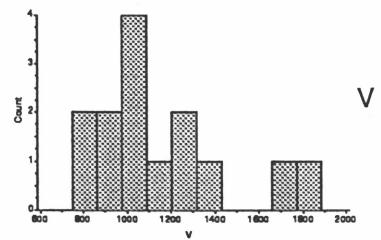

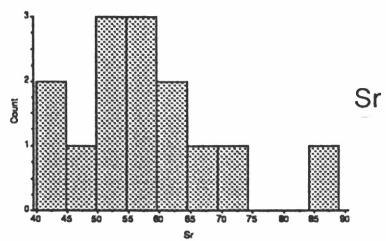

APPENDIX 8

Frequency Distributions - Coarse Lag

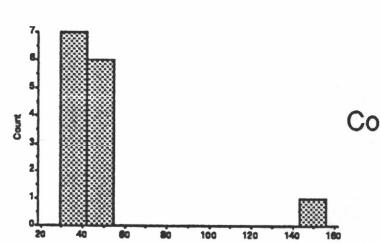

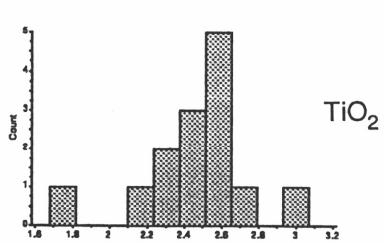

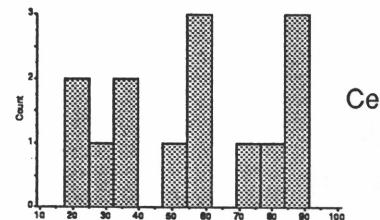

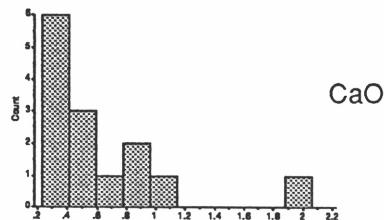

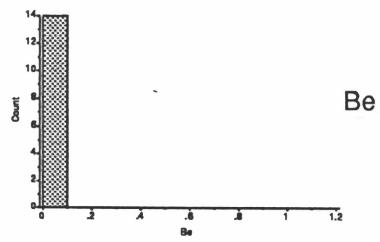

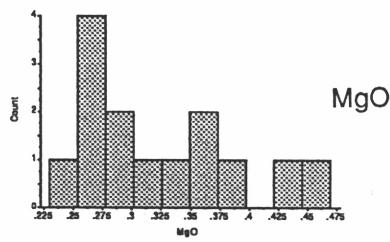

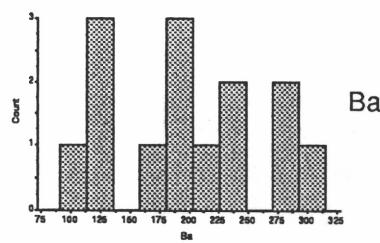

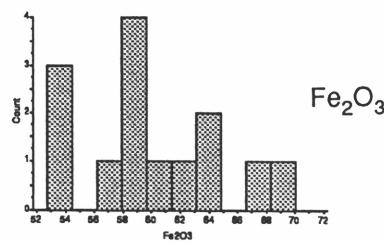

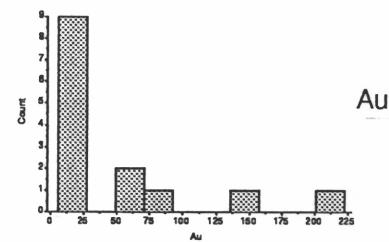

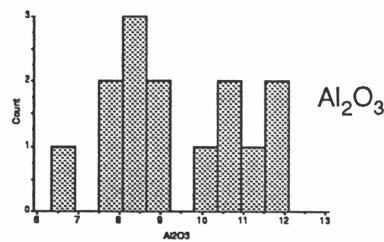

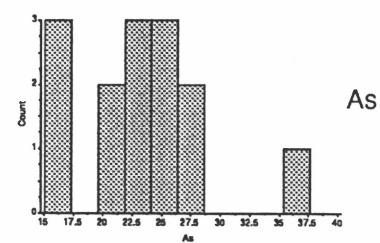

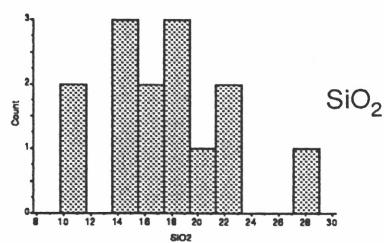

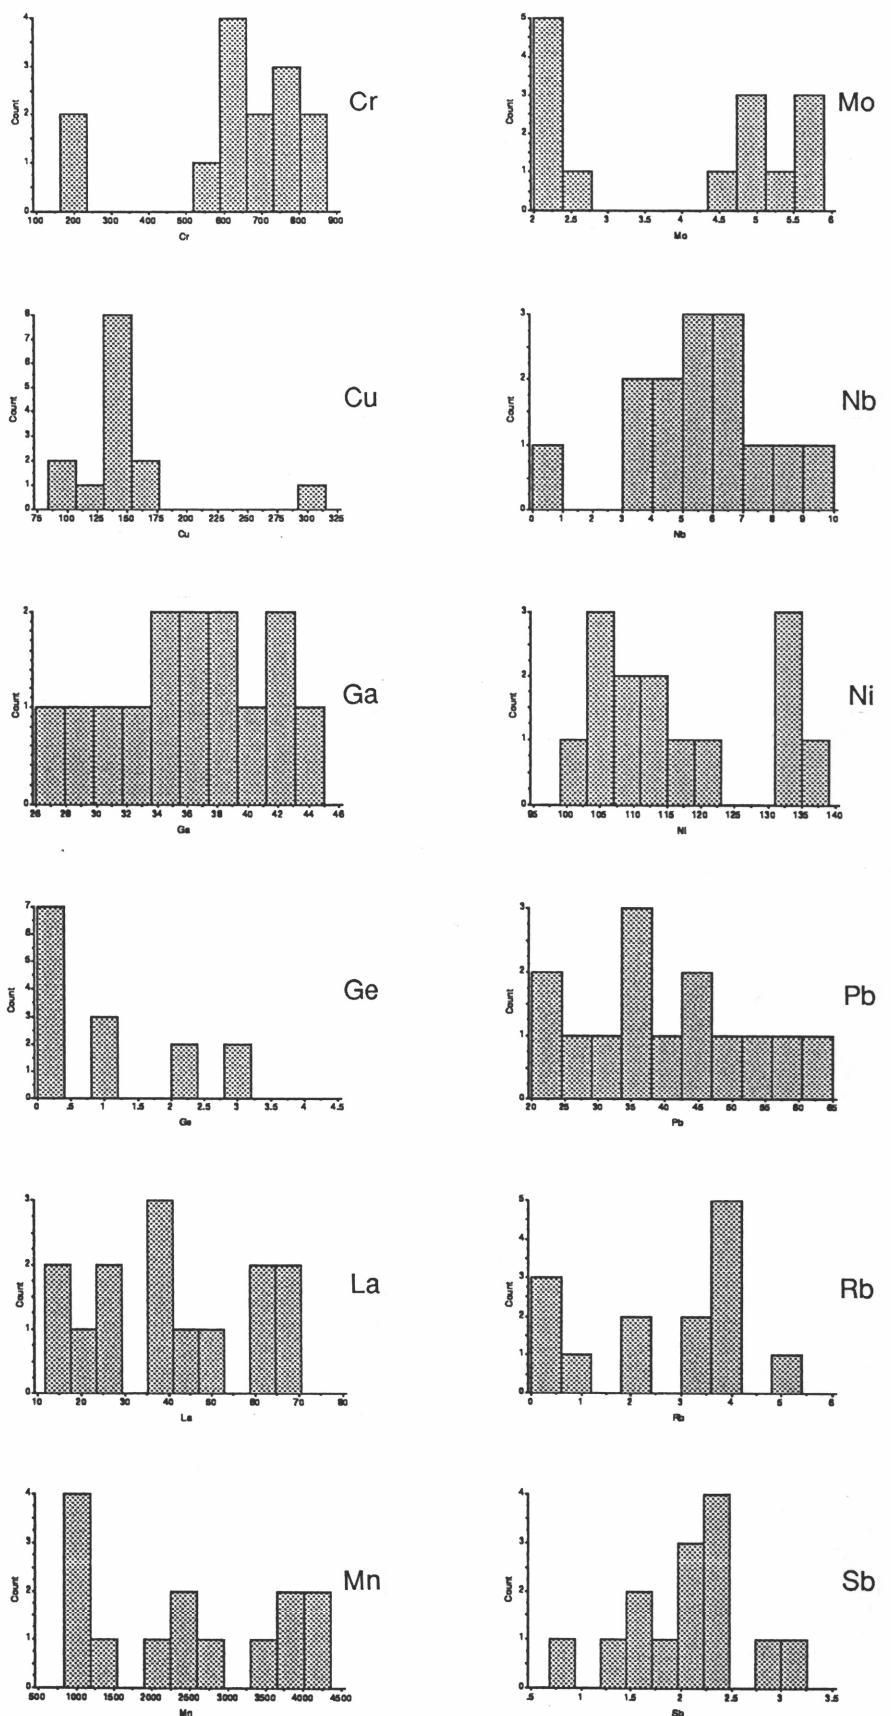

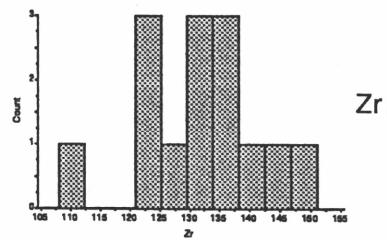

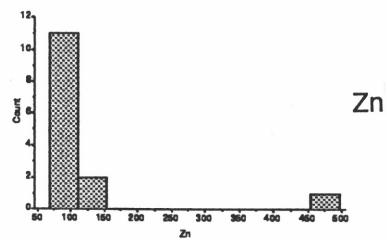

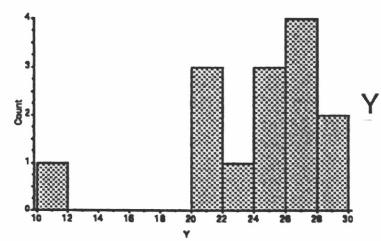

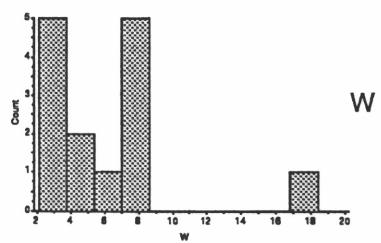

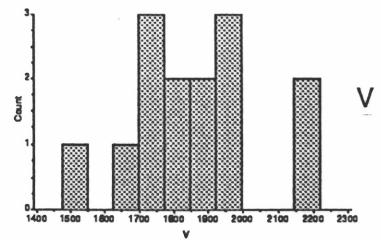

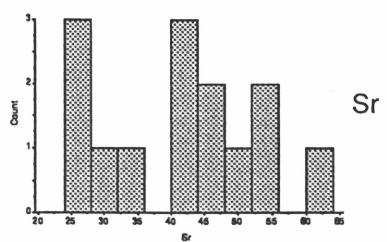

APPENDIX 9

Frequency Distributions - Fine Lag

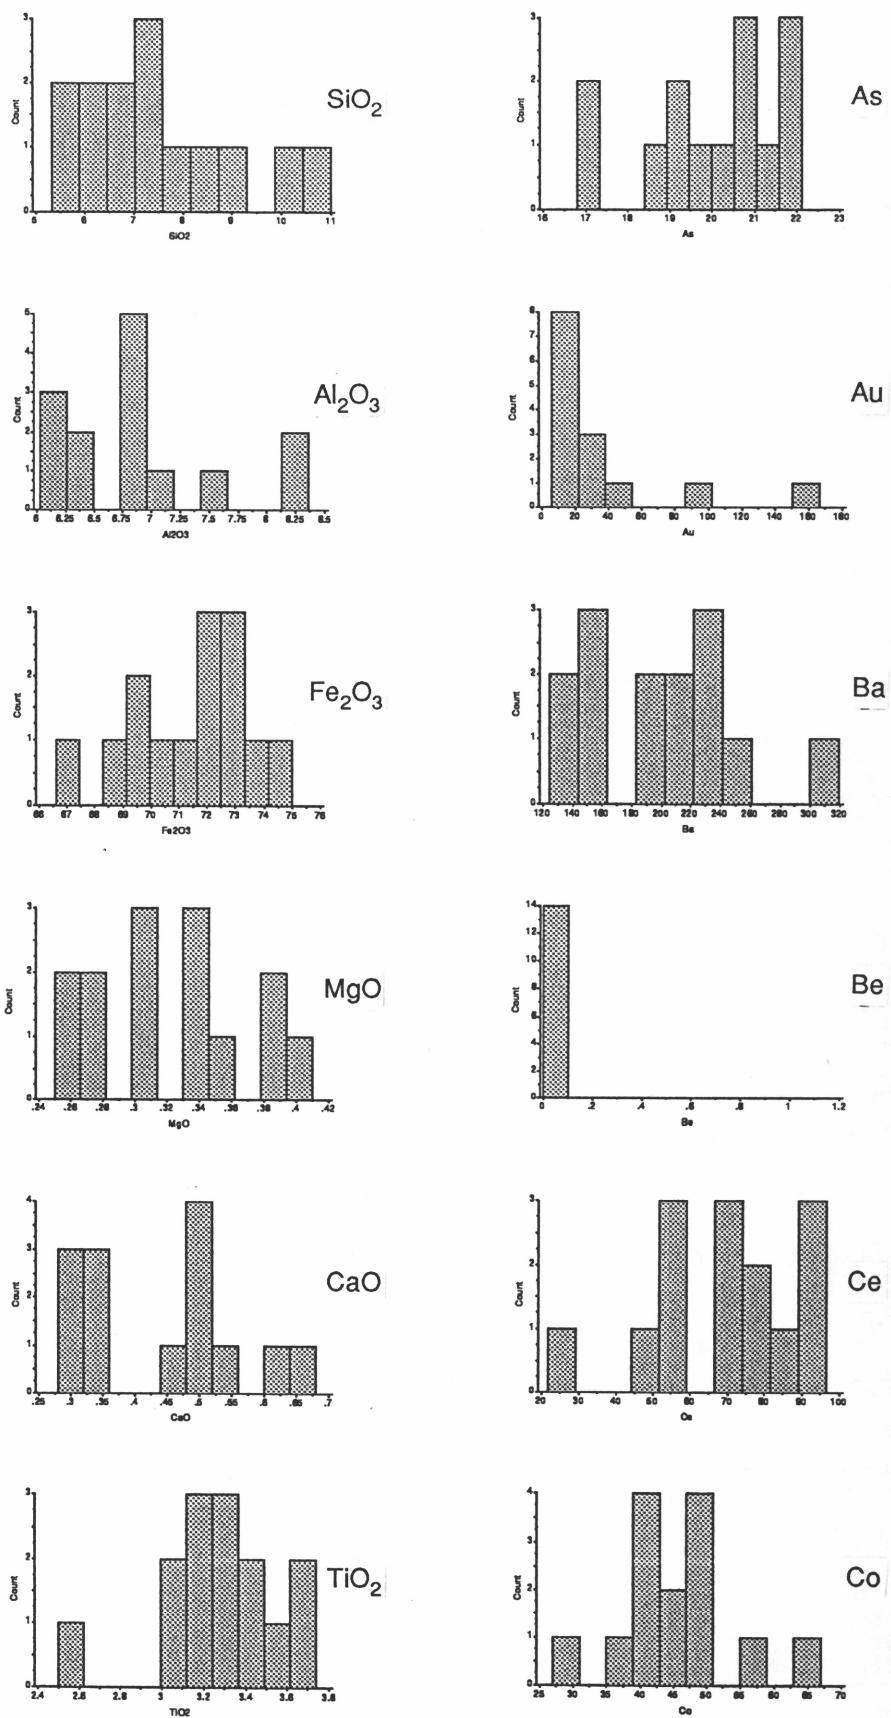

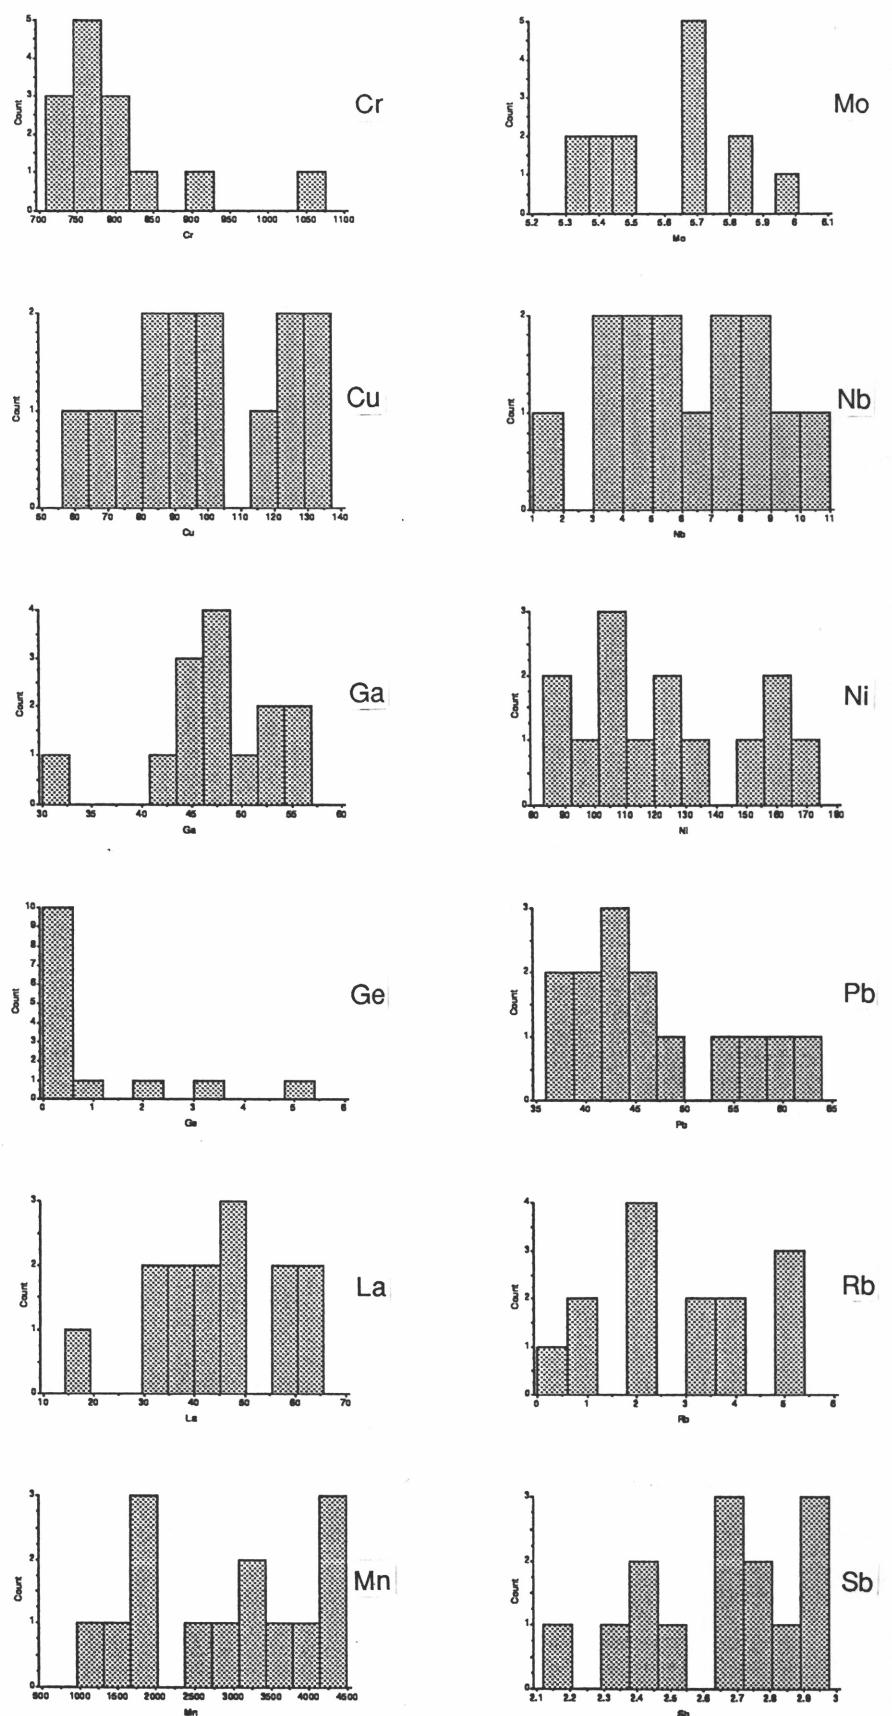

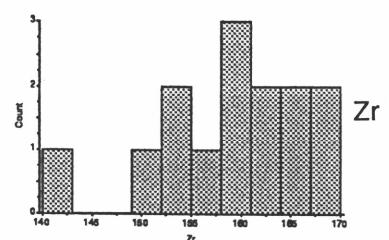

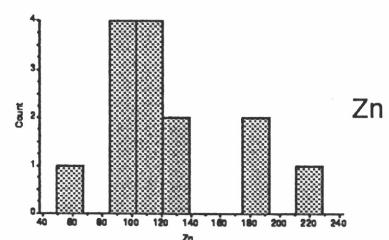

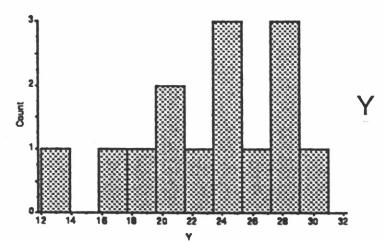

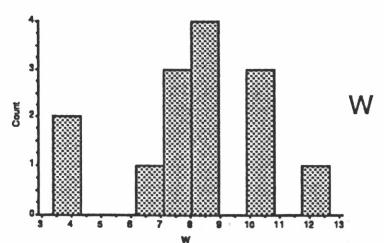

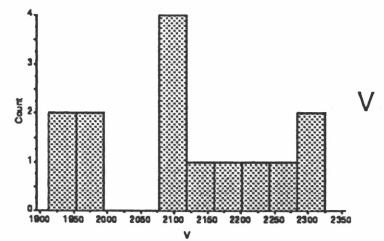

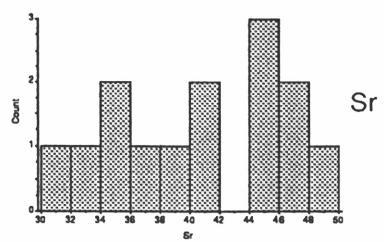

APPENDIX 10

Frequency Distributions - Fine Lag Magnetic

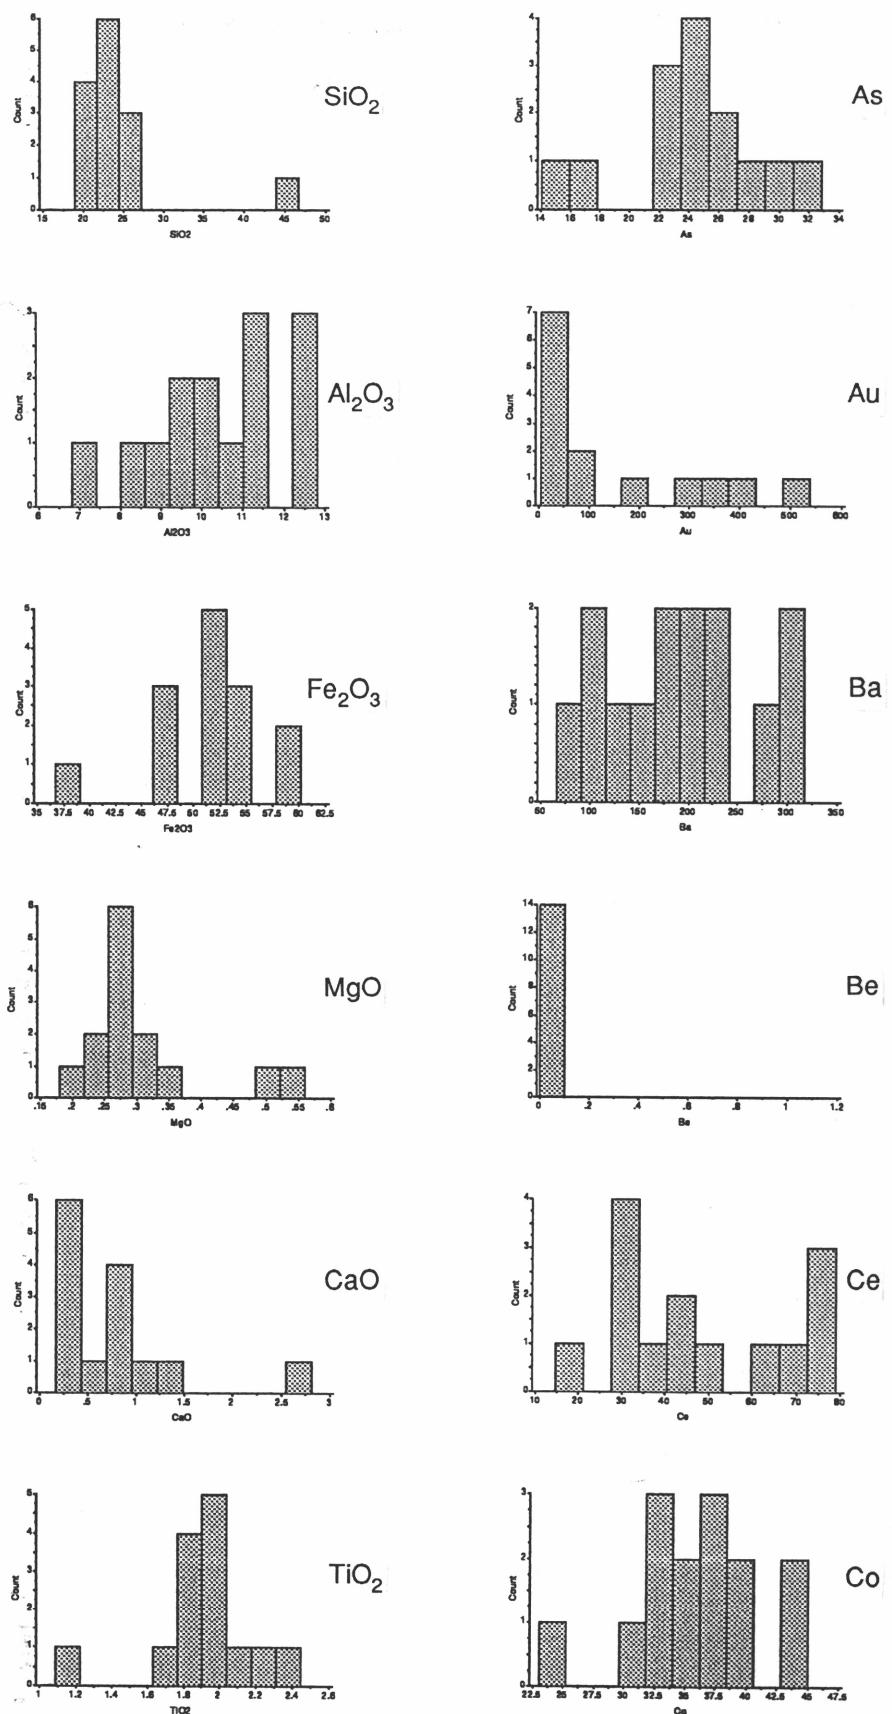

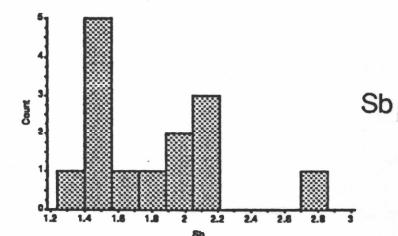

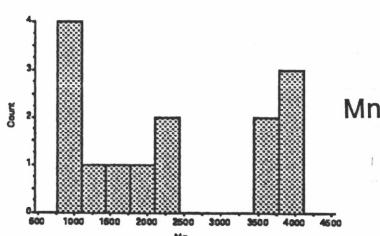

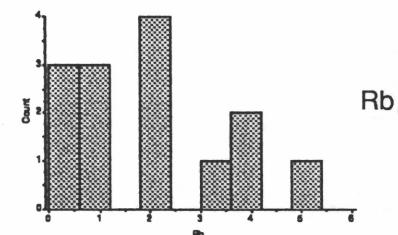

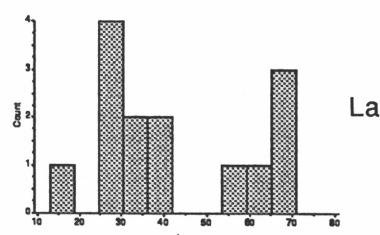

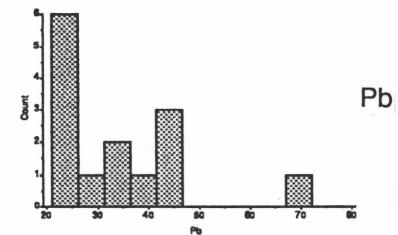

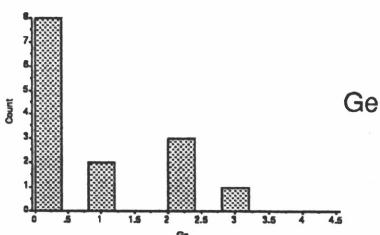

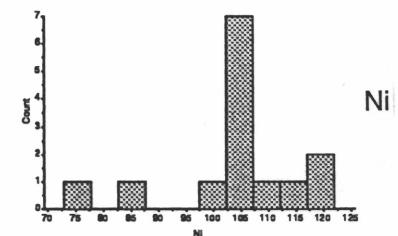

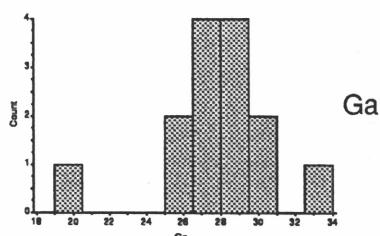

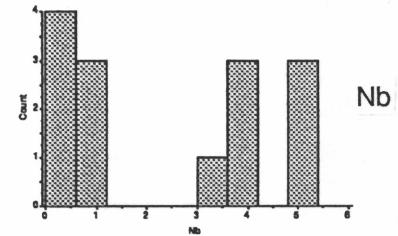

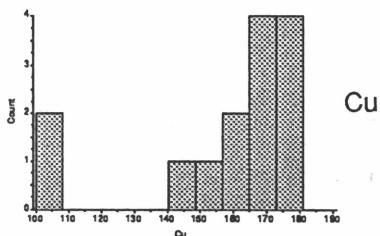

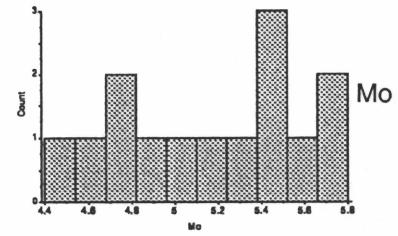

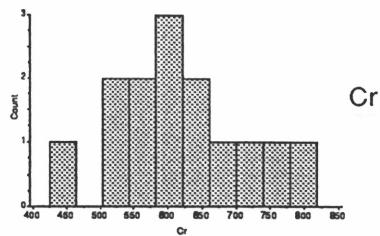

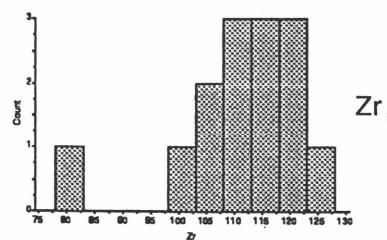

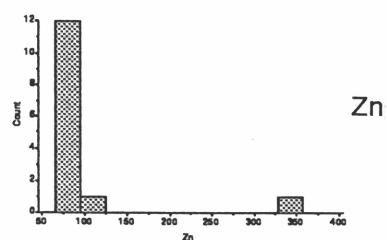

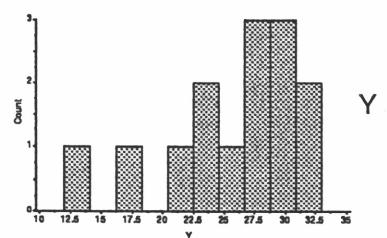

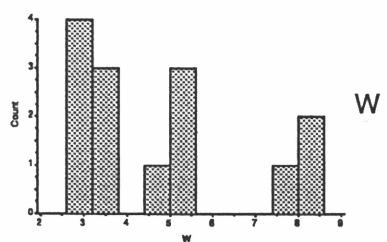

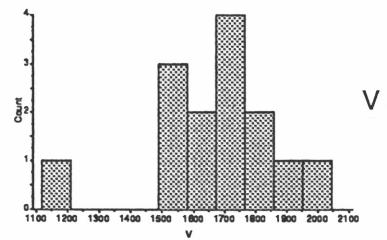

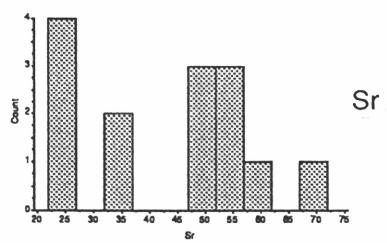

APPENDIX 11

Frequency Distributions - Fine Lag Non-Magnetic

APPENDIX 12

Correlation Matrices - Transformed Data

Significance:

95% > 0.458	
99% > 0.612	
99.9% > 0.780	

See Appendix 17 for transforms used

APPENDIX 13

Petrography of Soil Fractions

APPENDIX 13

Petrography of Soil Fractions

Sample LIC-53: 701- 2000 µm. It is dominated by angular fragments of deep brown to black goethite and minor chips of vein quartz, with a little tourmaline. The quartz varies widely from white, 'buck' quartz, through clear, well-crystalline, glassy quartz, which is the most abundant, and a very few rounded quartz grains. The glossy black fragments have partial nodular rims and are clearly fragments of larger nodules. The red brown fragments are less dense than the black glossy fragments and presumably consist of iron-stained clays. The yellow fragments are less abundant than the other two types and presumably consist of goethite-stained clays.

Sample LIC-53: 500-710 µm. Similar but the proportion of quartz is a little higher.

Sample LIC-53: 250-500 µm. Angular to subangular chips of vein quartz dominate the goethitic fragments. Some of the quartz is partly coated with goethite and there are minor schorlomite grains. The proportion of glassy quartz is greater than in the previous sample. Some grains appear to show terminations and all the quartz is very angular, suggesting little transport.

Sample LIC-53: 150-250 µm. This is similar to the previous sample but it is contaminated with clay. Most of the quartz is very angular, though there are a very few worn and rounded grains.

Sample LIC-53: 75-150 µm. Goethite-rich fragments dominate the angular quartz slightly. There is a trace of microcline. Although most of the quartz is still angular, there is a higher proportion (10-20%) of rounded, worn grains and these are probably aeolian.

Sample LIC-53: <75 µm. This consists largely of goethite and clay with a trace of tourmaline. The material is too fine under the binocular microscope to determine if there are any aeolian grains.

Sample LIC-53: <4 µm. This is largely clay, with a trace of tourmaline.

Sample LIC-58: >2000 µm. This consists largely of angular goethitic granules.

Sample LIC-58: 710-2000 µm. Goethite-rich fragments dominate the fragments of vein quartz and minor tourmaline. The quartz is very variable, both white 'buck' quartz and clear types being represented, but it is all angular, except for 1-2% of frosted, rounded grains.

Sample LIC-58: 500-710 µm. There are approximately equal proportions of vein quartz and goethitic granules, with a significant amount of tourmaline. The quartz is all angular, and there are a few angular, cleavage fragments of fresh K feldspar.

Sample LIC-58: 250-500 µm. Subangular vein quartz grains dominate the goethitic granules and there is significant tourmaline and minor microcline. The quartz is almost all angular though there are a very few frosted, rounded grains.

Sample LIC-58: 150-250 µm. Subangular quartz grains dominate the granular goethite. There is also minor tourmaline and a trace of weathered microcline. The quartz shows slight coating with goethite. The proportion of frosted, rounded grains is slightly greater.

Specimen LIC-58: 75-150 µm. There is much clay and minor quartz with a significant proportion (>10%) of rounded, frosted grains.

Specimen LIC-58: <75 µm. This is dominantly clay pellets with a trace of quartz.

Specimen LIC-58: <4 µm. Clay, here, forms small flakes, a few clusters and pellets.

APPENDIX 16

Petrography of Coarse Lag

APPENDIX 16

PETROGRAPHY OF COARSE LAG

LOI-03. This consists of two fragments, one is mauvish grey and is rich in goethite, the other is dark grey, has an internally pisolithic structure and is hematite-rich. The goethite-rich fragment is porous and contains numerous layer-silicate relics, probably after smectite. The hematitic fragment has a probable ferruginised saprolite (layer silicate) fabric, which has been extensively blurred by replacement of the goethite by hematite. Most of it consists of structures of secondary hematite and intimately mixed hematite and goethite. The pisolithic structures are joined by a porous, hematite-rich cement.

LOI-04. This consists of four fragments, two are hematite rich and two are rich in ferruginous clay. The hematite-rich fragments consist of several generations of porous, secondary hematite and goethite. Large voids have been filled with a younger goethite with a cuspatate fabric (Figure 11G). The fragments of ferruginous clay consist of composite fragments, some partly coated in goethite with an internally pisolithic structure, and are set in goethitic clay. Voids and channelways in the cementing clay are lined and recemented with goethite.

LOI-05. Of the three fragments in the section, one is a ferruginised fragment of saprolite. It consists of a spongy mass of goethite set with layer-silicate pseudomorphs. The fabric has been partly dissolved and it is cut by voids and channelways. Another is rich in hematite and consists of iron-cemented pisolithic material. The centres of these pisoliths consist either of massive hematitic goethite or, in turn, consist of micro pisolithic structures. The margins of the fragment shows extensive dehydration cracking, due to conversion of goethite to hematite. The third appears to have been a ferruginised saprolite but it has been extensively etched and dissolved and parts have been filled with spongy goethite and mixed goethite and hematite.

LOI-06. Although the three fragments in the section are dominated by reds and browns rather than by the more usual greys, they are all very different from one another. One consists of subangular fragments of mixed goethite and hematite, with secondary fabrics, set in a mass of quartz shards, cemented by goethitic clay. Some of the goethitic clay shows cuspatate void-filling structures. There are no visible original fabrics. Both the other fragments contain relics of original fabrics. One consists of several fragments of deeply etched and partly dissolved ferruginised saprolite, set in massive to spongy secondary goethite. Each fragment has a subtly different fabric from its neighbour, though all consist of layer-silicate (clay) pseudomorphs in varied states of preservation. The other is similar though it also shows numerous accordion structures (Figure 11H).

LOI-07. The three fragments that make up this section are very different in appearance. One is deep red, one is yellow-brown and the third is very dark brown to black. The red fragment has a partial cutan of layered goethite and it consists largely of goethitic clay with a rather confused fabric. Parts of this clay have been etched away and the resultant voids and channelways have been lined with goethite. The black fragment consists of massive to spongy, bright goethite and even brighter dehydration-cracked hematite, with no visible primary structures. The yellow fragment consists of spongy, secondary goethite, which has been considerably etched and the voids lined with goethite.

LOI-08. One fragment is of dark quartz, with a few small pockets of goethite and goethitic clay. The other two are ferruginous. One consists of nodules of secondary goethite and hematite, set in spongy goethite and shards of quartz (Figure 11A). The other is saprolitic and consists of poorly preserved clay structures replaced by goethite. This fabric has been severely etched and the resultant voids have been filled with goethitic clay.

LOI-09. Both fragments, one a deep honey-brown and the other mottled red and grey, contain poorly preserved relics of layer silicates, largely replaced by massive goethite and by spongy secondary goethite respectively.

LOI-10. One of the fragments consists entirely of spongy secondary goethite with some small pseudomorphs after fine-grained pyrite (Figure 11F). This specimen is close to the ore subcrop and probably represents the gossan. The other contains some remnants of layer silicate pseudomorphs (Figure 11B) but the remainder is spongy secondary goethite, goethitic clay and dehydration-cracked hematite-goethite, cut by a web of voids and solution channels, many of which are lined with goethite (Figure 11D). There is evidence of several stages of solution, clay-filling and recementing by iron oxides. The third is saprolitic and consists of well-preserved layer silicate pseudomorphs but this is pockmarked with vermiform voids which are lined with a thin layer of colloform goethite.

LOI-11. Of the three fragments, one is red-brown and the others metallic grey. The red-brown fragment consists largely of massive, cracked goethite and hematitic goethite, with a few, very imperfectly preserved

remnants of layer silicate pseudomorphs. Of the two grey fragments, one consists of fragments of massive, secondary, hematitic goethite, set in later phases of hematitic goethite. The other has a similar mineralogy but shows incipient pisolith structures and some accordion structures set in spongy goethite.

LOI-12. Two of the fragments are red-brown and the third is metallic-grey. Both the red-brown fragments consist of goethite and goethitic clay, one being more clay-rich than the other. The more goethite-rich of the two shows some very well-preserved layer silicate fabrics pseudomorphed in goethite. In other parts, the goethite has recrystallised to a secondary fabric containing lozenge-shaped crystals of hematite. In the red fragment there is more clay, less goethite and the hematite occurs in small, lenticular aggregates of granules. The grey fragment is rich in goethite and hematite and shows numerous moderately well- to poorly-preserved layer silicate pseudomorphs and some accordion structures, all set in spongy secondary goethite and hematite.

LOI-13. There are two fragments, one brown, the other grey. The brown fragment, though poorer in goethite and richer in goethitic clay, shows well-preserved original fabrics. The grey fragment shows largely stellate secondary goethite (Figure 11E), possibly after original carbonates, with a hint of preserved layer silicate fabrics.

LOI-14. One fragment shows hematitic goethite stellate structures, with a hint of layer silicate structure. This has been extensively dissolved and is cross cut by numerous channelways. The other is more hematite-rich, has a generally spongy, secondary fabric and contains numerous voids now filled with iron oxides with a cuspatate fabric. There are a few hints of layer-silicate fabrics. The third fragment is also hematitic but it shows both layer silicate fabrics and accordion structures set in and invaded by massive secondary goethitic hematite.

LOI-71. One fragment is very rich in layer-silicate structures, preserved in hematitic goethite. This fabric is cut and invaded by massive goethitic hematite. Another fragment has a stellate structure with numerous solution channels and incipient pisoliths. The third contains less iron oxides and more clay and shows only secondary structures.

LOI-72. The fragments from this section are more diverse than most, possibly reflecting a geologically more complex area. Although one fragment shows poorly preserved layer silicate structures, it has been intensively dissolved and secondary goethite, with cuspatate structures has been deposited in the voids. This has been re-dissolved and recemented by massive to spongy hematitic goethite. Another fragment is rich in goethitic clay but it also contains numerous voids which are lined with colloform goethite. The third fragment is very complex and consists of hematitic nodules, with a variety of fabrics, from massive secondary, through internally clastic to internally pisolithic. These are set in a matrix of similar material cemented by goethite.

53>8. It consists of black and dark red-brown nodular fragments, deep honey brown clasts, yellow brown and red-brown clasts and fragments of quartz. The black fragments consist of spongy goethite with a distinct possibly pseudomorphic gneissose fabric. Some show some poorly preserved layer silicate (?smectite) fabrics and a well preserved relic of tourmaline (Figure 11C). The red-brown fragments consist of spongy goethitic clay with small patches of goethite and lozenge-shaped crystals of hematite

58>8. It consists of black, nodular fragments, deep red-brown fragments and yellow brown clasts as well as a few pieces of quartz. Again the nodular black material consists of massive to spongy hematitic goethite, in which are set some layer silicate pseudomorphs, some incipient pisolithic structures. The red-brown fragments consist of goethitic clay with scattered voids, lined with goethite. Some layer silicate relics are preserved in the clay.

53>22 and 58>22. These are similar to the above, showing a similar variety of clast and similar internal fabrics but the material in being finer-grained, is more fragmentary.

53>30 and 58>30. Similar to the above but the proportion of quartz fragments and clay-rich fragments has increased at the expense of the nodular black goethite and hematite-rich material. Only one fragment found which could be gossanous.

53>60 and 58>60. The trend towards more abundant quartz is even more obvious here. Pisolithic structures in these materials are extremely rare.

The generalised power transformed value y is calculated from an untransformed x as:-

$$y = (x^{\lambda} - 1)/\lambda$$

but where $\lambda = 0$ then:-

$$y = \ln(x)$$

For more detail, refer to Box and Cox (1964) and Grunsky (1991).

APPENDIX 18

Soil Pilot Study and Soil Fractionation Techniques

APPENDIX 18

Soil Pilot Study and Soil Fractionation

Pilot Study

Size fraction analysis of selected samples formed a pilot study to aid the design of the final soil fractionation scheme, described in Section 3. Small soil sub-samples were split from two representative samples for preliminary size fraction analysis. The subsamples were first disaggregated by hand in an agate mortar. They were dry sieved on a six sieve stack without brushing to yield >2000, 2000-710, 710-500, 500-250, 250-142, 142-75 and <75 µm fractions. The <75 µm fraction was shaken with water and allowed to settle for 20 minutes through 100 mm. The clay that remained in suspension (nominally <4 µm fraction) was siphoned off. This clay, and the sedimented residue (4-75 µm), which still contained some clay, were dried by evaporation. Each of these eight fractions was weighed and the percentage yields calculated. All size fractions, except the <4 µm fraction, were repeatedly cleaned ultrasonically in water until the yield of clay was minimal, prior to petrographic study. The resultant preparation scheme for the complete soil sample set is given below.

Soil Sample Preparation and Clay Fractionation

Lumps in each soil sample were broken by hand in an agate mortar until the sample passed a 4 mm screen. Vegetable matter and any large stones were rejected. The sieved soil was coned and split into three parts on a paper sheet. The first part was retained for reference, the second was milled in a case-hardened steel mill and submitted for analysis as a whole. The third was separated into three components, as shown below, and each analysed separately.

The third sub-sample was first wet sieved in nylon and polystyrene by hand. Three size fractions were collected (2000-600, 600-75 and <75 µm). All fractions were shaken with de-ionised water to which a few drops of analytically pure, concentrated NH₄OH had been added to disperse any adhering clay-sized particles. Both the 2000-600 and the 600-75 µm fractions were repeatedly subjected to ultrasonic agitation. The clay-bearing liquid was decanted through a 75 µm screen and added to the <75 µm fraction. After several changes of water and ultrasonic treatment, the clean 710-2000 µm fraction, rich in ferruginous granules, was dried at 95°C and the sandy 75-710 µm fraction was discarded. This rather involved method (Figure A) was necessary to maximise the yield of clay to obtain sufficient for analysis. The clay separation method could have been simplified if a larger soil sample (>3 kg) had been collected (Figure B).

The <75 µm suspension was made up to 3.5 litres with de-ionised water. Analytically pure, concentrated NH₄OH was added dropwise, until a pH of 8.0 (measured by pH meter) was achieved, to disperse the clays. The suspension was allowed to settle for 20 minutes through a depth of 100 mm. At this stage, only particles <9 µm would still be in suspension (Stokes Law). Most of the suspension (>95%) was decanted using a specially constructed PVC siphoning tube. The <75 µm sediment was sedimented again to ensure that most of the clay had been removed and was then dried at 95°C, disaggregated in agate and packaged for analysis.

The clay-rich suspension was acidified dropwise with analytically pure, concentrated HCl to a pH of 4.0, to flocculate and precipitate the clays. Some samples consumed a little more acid than others. In these, the pH tended to stabilise at pH 6-7, apparently due to the buffering effect of minor calcite and, on addition of further HCl, the pH finally decreased to 4.0. After settling for 30 minutes or more, the overlying liquid was withdrawn and the clay floc dried at 95°C and disaggregated by hand in agate prior to analysis. Despite adequate drying, the clays tended to 'ball' and stick to the agate surfaces.

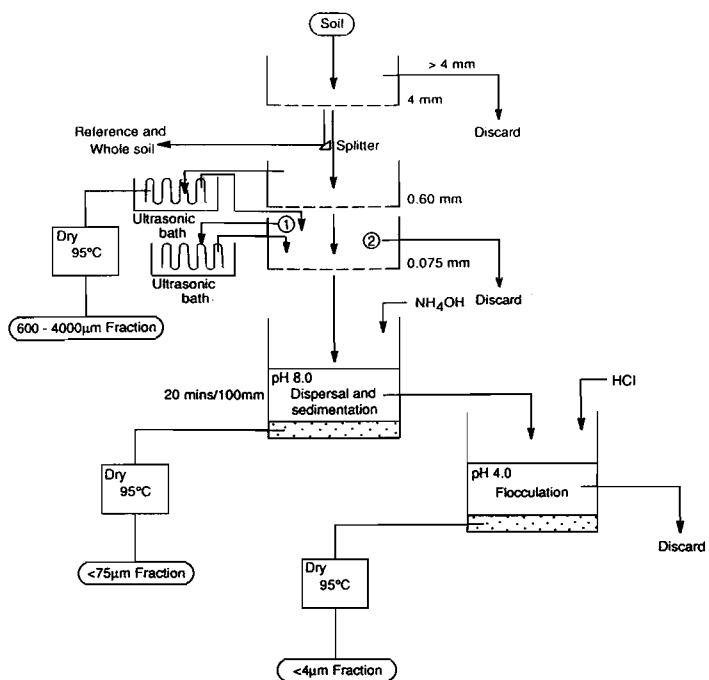

Figure A. Sample preparation flow chart.

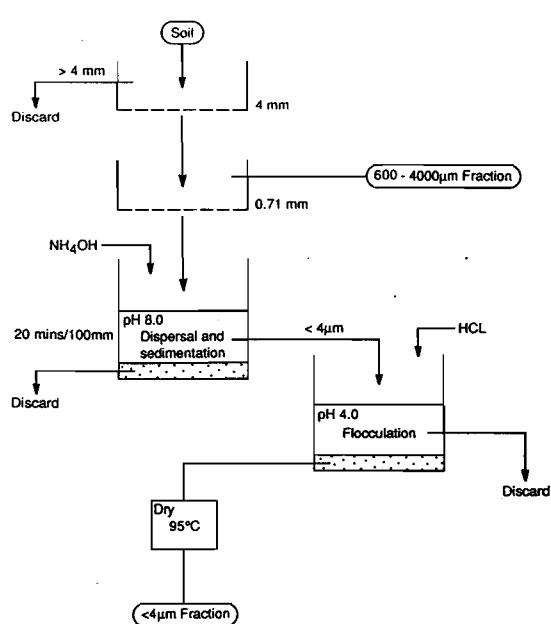

Figure B. Simplified soil fractionation flow chart.

Clay dispersion, using NH₄OH, significantly improved the yield of clay and was considered to be far less likely to contaminate the sample than technical grade polyphosphate (e.g. tetra sodium pyrophosphate), which would normally be used for this purpose. The short exposure (about one hour) of the clays to a pH range of 4.0-8.0, which is not extreme in the natural environment, and the use of pure water and reagents, was not regarded as likely to have significantly modified the clay chemistry. Clay flocculation at pH 4.0 was far quicker and more efficient than centrifugal separation of the dispersed clay.

Clay size separation, using this technique, is approximate. Stokes law assumes spherical particles, laminar flow and requires accurate values for the viscosity of the fluid and the densities of both fluid and particles. Clay particles are platelike and the clays contain an appreciable component of attached iron oxides, so varying their densities, fluid dynamics and hence settling velocities. Work by Robertson (1990) on similar soil clay separations from Beasley Creek showed that the clay fraction is nominally <4 µm (i.e. >95% are <4 µm).
