RESEARCH ARISING FROM CSIRO/AMIRA REGOLITH GEOCHEMISTRY PROJECTS 1987-1993

In 1987, CSIRO commenced a series of multi-client research projects in regolith geology and geochemistry which were sponsored by companies in the Australian mining industry, through the Australian Mineral Industries Research Association Limited (AMIRA). The initial research program, "Exploration for concealed gold deposits, Yilgarn Block, Western Australia" (1987-1993) had the aim of developing improved geological, geochemical and geophysical methods for mineral exploration that would facilitate the location of blind, buried or deeply weathered gold deposits. The program included the following projects:

P240: Laterite geochemistry for detecting concealed mineral deposits (1987-1991). Leader: Dr R.E. Smith. Its scope was development of methods for sampling and interpretation of multi-element laterite geochemistry data and application of multi-element techniques to gold and polymetallic mineral exploration in weathered terrain. The project emphasised viewing laterite geochemical dispersion patterns in their regolith-landform context at local and district scales. It was supported by 30 companies.

P241: Gold and associated elements in the regolith - dispersion processes and implications for exploration (1987-1991). Leader: Dr C.R.M. Butt.

The project investigated the distribution of ore and indicator elements in the regolith. It included studies of the mineralogical and geochemical characteristics of weathered ore deposits and wall rocks, and the chemical controls on element dispersion and concentration during regolith evolution. This was to increase the effectiveness of geochemical exploration in weathered terrain through improved understanding of weathering processes. It was supported by 26 companies.

These projects represented "an opportunity for the mineral industry to participate in a multi-disciplinary program of geoscience research aimed at developing new geological, geochemical and geophysical methods for exploration in deeply weathered Archaean terrains". This initiative recognised the unique opportunities, created by exploration and open-cut mining, to conduct detailed studies of the weathered zone, with particular emphasis on the near-surface expression of gold mineralisation. The skills of existing and specially recruited research staff from the Floreat Park and North Ryde laboratories (of the then Divisions of Minerals and Geochemistry, and Mineral Physics and Mineralogy, subsequently Exploration Geoscience and later Exploration and Mining) were integrated to form a task force with expertise in geology, mineralogy, geochemistry and geophysics. Several staff participated in more than one project. Following completion of the original projects, two continuation projects were developed.

P240A: Geochemical exploration in complex lateritic environments of the Yilgarn Craton, Western Australia (1991-1993). Leaders: Drs R.E. Smith and R.R. Anand.

The approach of viewing geochemical dispersion within a well-controlled and well-understood regolith-landform and bedrock framework at detailed and district scales continued. In this extension, focus was particularly on areas of transported cover and on more complex lateritic environments typified by the Kalgoorlie regional study. This was supported by 17 companies.

P241A: Gold and associated elements in the regolith - dispersion processes and implications for exploration. Leader: Dr. C.R.M. Butt.

The significance of gold mobilisation under present-day conditions, particularly the important relationship with pedogenic carbonate, was investigated further. In addition, attention was focussed on the recognition of primary lithologies from their weathered equivalents. This project was supported by 14 companies.

Although the confidentiality periods of the research reports have expired, the last in December 1994, they have not been made public until now. Publishing the reports through the CRC LEME Report Series is seen as an appropriate means of doing this. By making available the results of the research and the authors' interpretations, it is hoped that the reports will provide source data for future research and be useful for teaching. CRC LEME acknowledges the Australian Mineral Industries Research Association and CSIRO Division of Exploration and Mining for authorisation to publish these reports. It is intended that publication of the reports will be a substantial additional factor in transferring technology to aid the Australian Mineral Industry.

This report (CRC LEME Open File Report 56) is a Second impression (second printing) of CSIRO, Division of Exploration Geoscience Restricted Report 394R, first issued in 1993, which formed part of the CSIRO/AMIRA Projects P240A and P241A.

APPENDIX 4

POWER TRANSFORMS APPLIED TO DATA VALUES FOR LAMDA (λ)

Element	λ	Element	λ
Si	0.50	Cu	0.35
Al	0.80	Ga	0.20
Fe	1.40	Ge	0.00
Mg	-0.15	Mn	0.50
Ca	0.00	Mo	0.00
Na	0.00	Nb	0.00
K	0.00	Ni	0.60
Ti	-0.18	Pb	0.10
Ag	-0.20	Sb	-0.14
As	0.10	Se	0.00
Au	-0.10	V	1.00
Ba	-0.17	W	0.00
Bi	0.00	Zn	0.10
Co	0.00	Zr	1.00
Cr	0.50		

The generalized power transformed value y is calculated from an untransformed x as:

$$y = (x^{\lambda-1})/\lambda$$

but where $\lambda = 0$ then:-

$$y = \ln(x)$$

For more detail, refer to Box and Cox (1964) and Grunsky (1991).

APPENDIX 5

CORRELATION AND SCATTERPLOT MATRICES OF GEOCHEMICAL DATA FROM VB-BOAGS AND EMU AREAS (TRANSFORMED DATA)

Location	Number	Confidence Limits		
		95%	99%	99.9
VB Boags	212	0.113	0.160	0.225
Emu	145	0.139	0.195	0.275

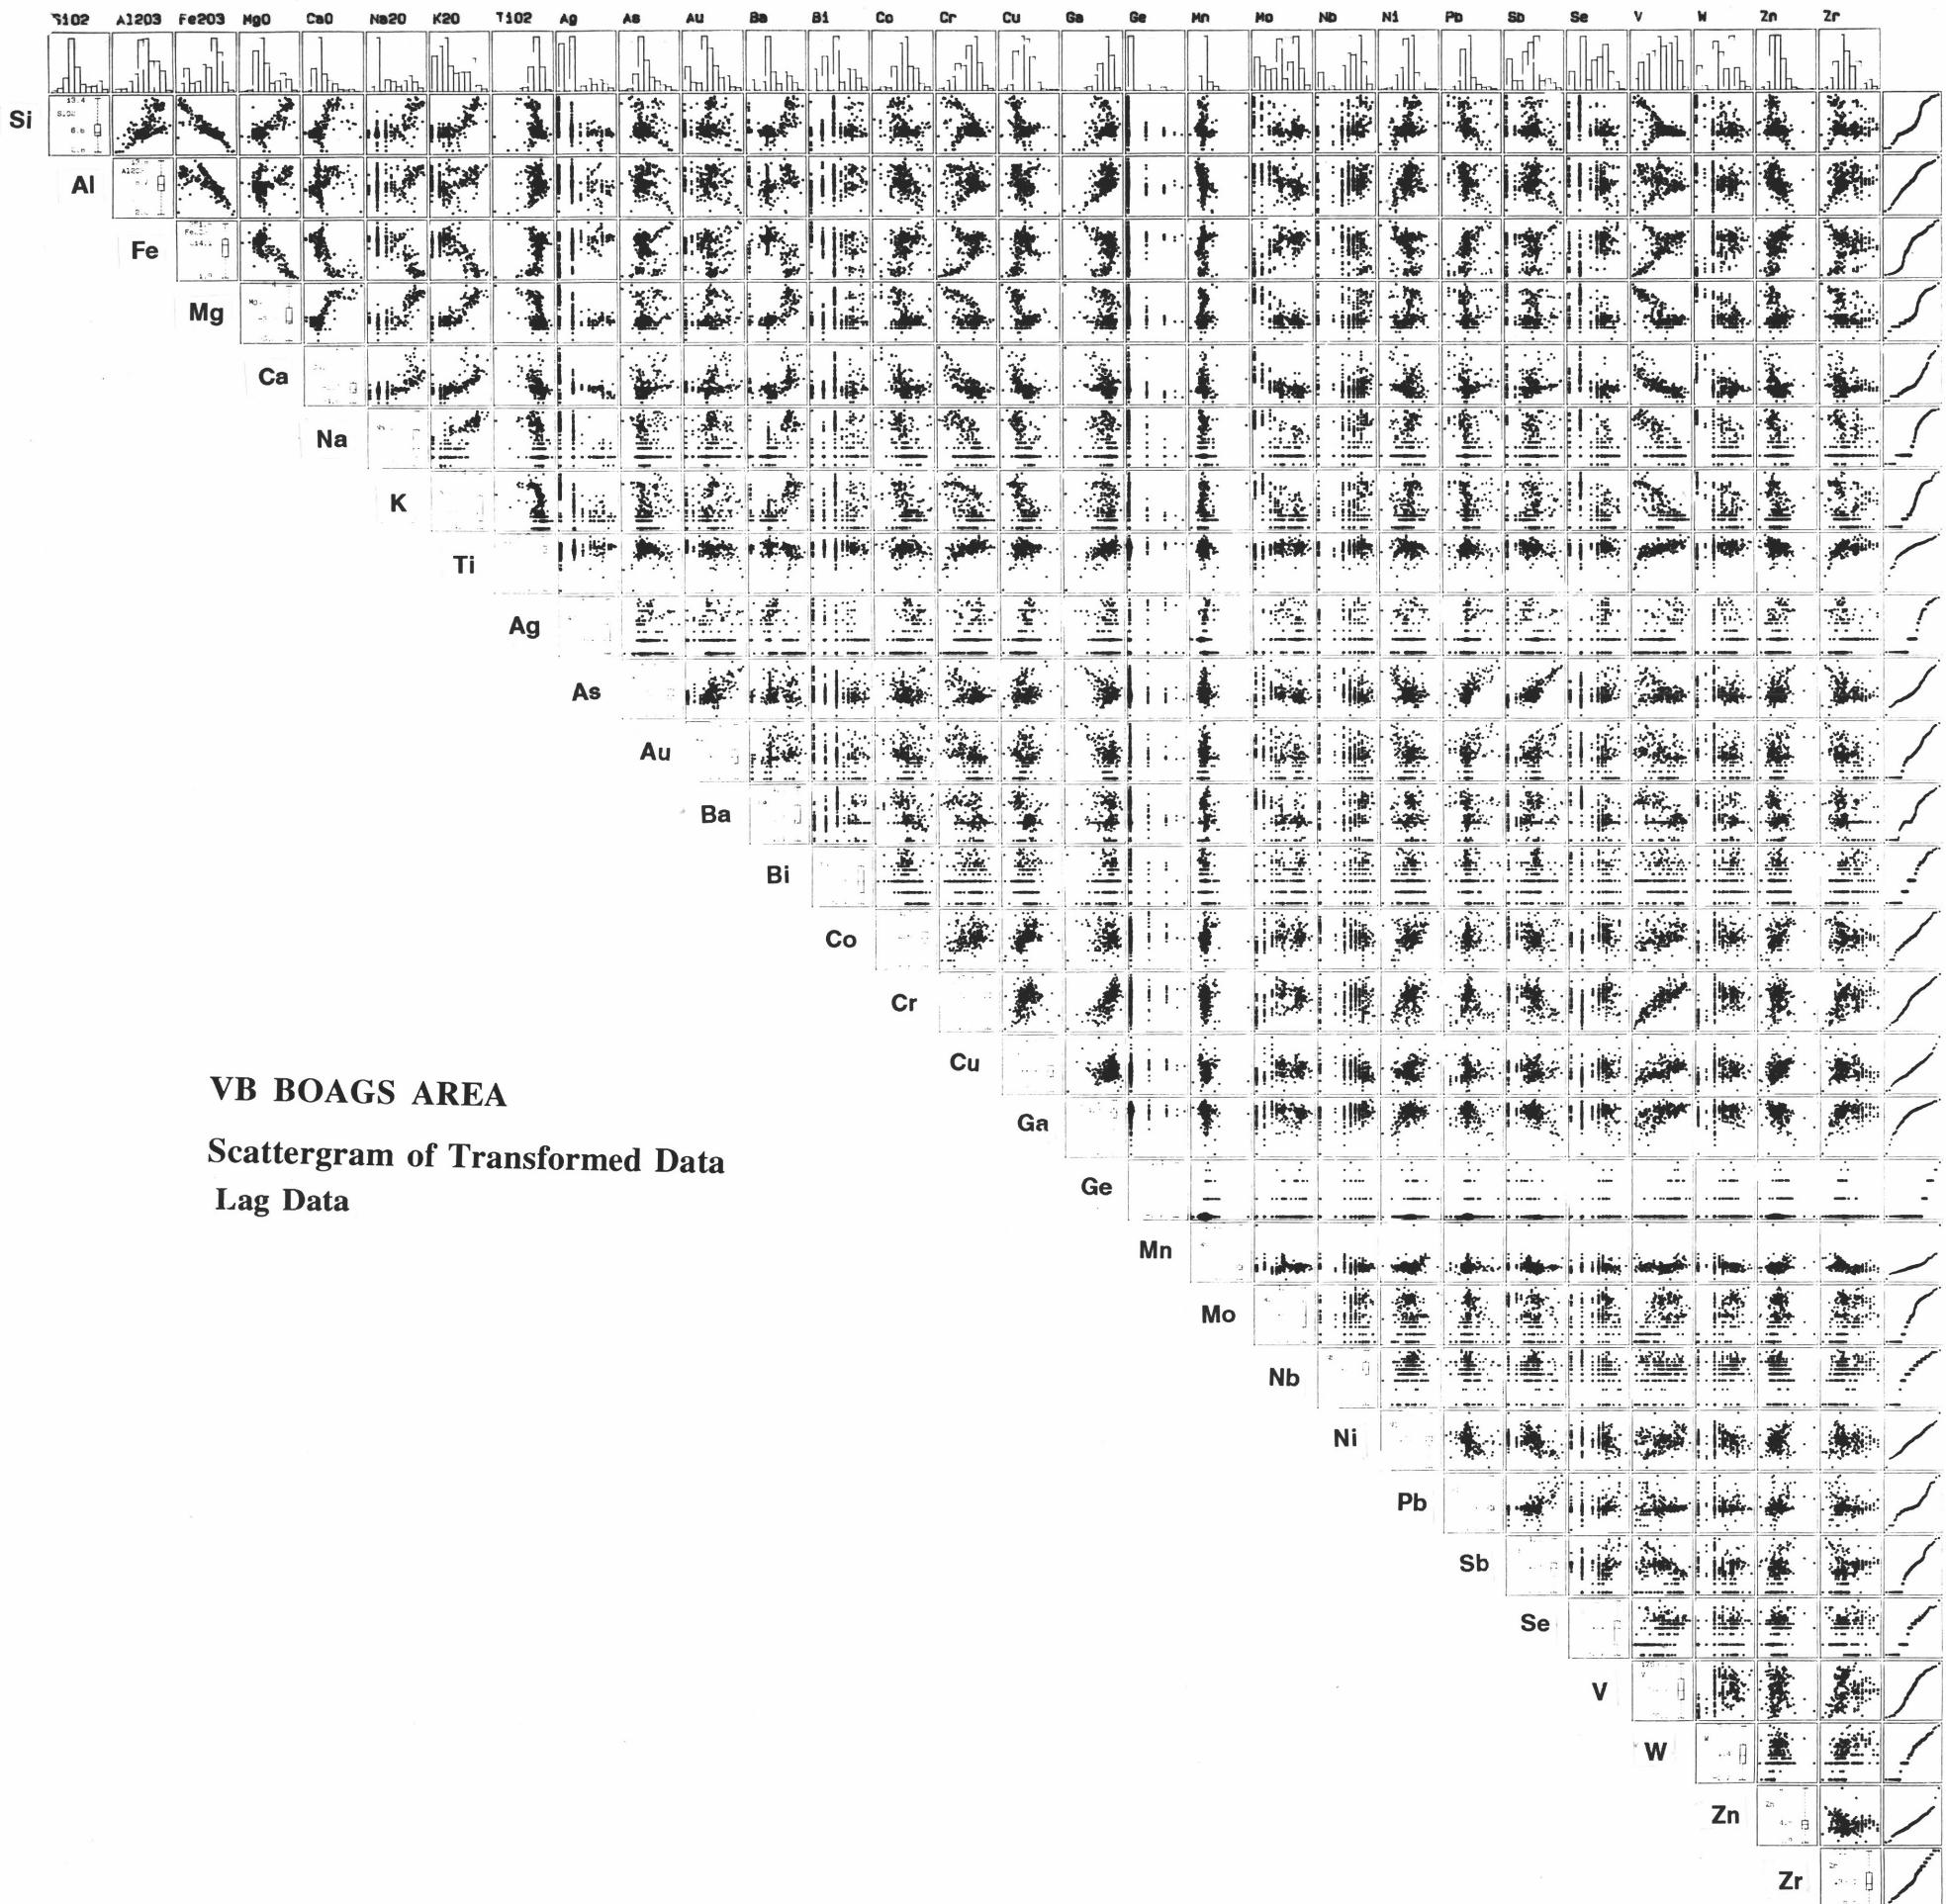

See Appendix 4 for details of transformations

APPENDIX 7

SYSTEMATIC PETROGRAPHY OF LAG

SYSTEMATIC PETROGRAPHY OF LAG

06-0190

This is rich in coarse, particularly linear mica flakes and equant subhedral hematite after magnetite. The magnetite pseudomorphs do not show trellis structures but internal brush polarization, suggesting an intermediate goethite phase which has been dehydrated to hematite. SEM examination of these pseudomorphs reveals a trace of As. The appearance and coarseness of the muscovite (K by SEM) suggests this may be part of a phyllitic alteration halo.

06-0191

Two of the fragments are black and the third dark brown. The brown fragment consists of a partly eroded fingerprint goethite fabric after kaolinite, typical of the saprolite of a mafic rock. The dark two are highly reflective and are composed of spongy, largely dehydrated goethite, showing secondary structures. One has a thin, partial cutan of ferruginous clay. There are some voids, now partly filled with cuspatate goethite.

06-0193

The three fragments show a wide variety of fabrics and compositions. Some show mixtures of relict mica and goethite pseudomorphs after kaolinite, set in lead grey goethite. These have been modified by a variety of secondary structures. One fragment contains a well-developed fingerprint fabric which has been largely recrystallised to accordion-structured kaolinite before partial replacement and preservation by goethite. Set in this fabric are patches and lozenges of hematite. Other parts consist of only secondary goethite structures, including botryoidal structures, dehydration structures and patches of intense iron oxide dissolution and redeposition.

06-0194

All three fragments show kaolinitic saprolitic fingerprint fabrics, overprinted to varying degrees by accordion structures, the whole now preserved in goethite. Laths and lozenges of hematite are common, as are numerous irregular voids. SEM examination of the kaolinite pseudomorphs indicates a very small amount of admixed K, typical of interlayered kaolinite and minor sericite, typical of weathering.

06-0226

Goethite pseudomorphs of fingerprint fabrics after saprolitic kaolinite predominate. There has been varying degrees of iron oxide dissolution to form channels and voids, with some iron oxide deposition as void linings.

06-0227

The rock has retained a strong schistose structure in which goethite has replaced a very fine-grained phyllitic structure of partly kaolinised muscovite, leaving the granular quartz unaltered. Set in it are 'eyes' of slightly coarser granular quartz, goethite replacing matted kaolinite with some vermicular accordion structures, and hematite pseudomorphs (martite) after magnetite, showing a trellis structure under crossed polarizers.

Some parts show alternating layers of phyllitic and quartzose material, either a graded argillaceous metasediment or the zebra-rock of Binns (1988), the phyllitic material, in part mica and in part kaolinite, has been largely replaced by and set in goethite.

06-1607

These are dominated by saprolitic fingerprint and accordion fabrics after kaolinite. Crystals of martite after primary magnetite or ilmenite are set in the saprolitic fabric which also shows slight dissolution along channels with partial filling by secondary goethite.

06-1624

Two of the three fragments in this section consist of very fine-grained kaolinite replaced and surrounded by lead-grey goethite, showing a classic fingerprint fabric, typical of the saprolite of a mafic rock. One has been intensively cracked and penetrated by solution channels, some of which are partly or completely filled with second generation goethite, with a slightly higher reflectivity. The third fragment is darker and rich in partly dehydrated goethite which appears to pseudomorph a complex magnetite fabric set in lead grey goethite which has been partly dissolved.
