RESEARCH ARISING FROM CSIRO/AMIRA REGOLITH GEOCHEMISTRY PROJECTS 1987-1993

In 1987, CSIRO commenced a series of multi-client research projects in regolith geology and geochemistry which were sponsored by companies in the Australian mining industry, through the Australian Mineral Industries Research Association Limited (AMIRA). The initial research program, "Exploration for concealed gold deposits, Yilgarn Block, Western Australia" (1987-1993) had the aim of developing improved geological, geochemical and geophysical methods for mineral exploration that would facilitate the location of blind, buried or deeply weathered gold deposits. The program included the following projects:

P240: Laterite geochemistry for detecting concealed mineral deposits (1987-1991). Leader: Dr R.E. Smith. Its scope was development of methods for sampling and interpretation of multi-element laterite geochemistry data and application of multi-element techniques to gold and polymetallic mineral exploration in weathered terrain. The project emphasised viewing laterite geochemical dispersion patterns in their regolith-landform context at local and district scales. It was supported by 30 companies.

P241: Gold and associated elements in the regolith - dispersion processes and implications for exploration (1987-1991). Leader: Dr C.R.M. Butt.

The project investigated the distribution of ore and indicator elements in the regolith. It included studies of the mineralogical and geochemical characteristics of weathered ore deposits and wall rocks, and the chemical controls on element dispersion and concentration during regolith evolution. This was to increase the effectiveness of geochemical exploration in weathered terrain through improved understanding of weathering processes. It was supported by 26 companies.

These projects represented "an opportunity for the mineral industry to participate in a multi-disciplinary program of geoscience research aimed at developing new geological, geochemical and geophysical methods for exploration in deeply weathered Archaean terrains". This initiative recognised the unique opportunities, created by exploration and open-cut mining, to conduct detailed studies of the weathered zone, with particular emphasis on the near-surface expression of gold mineralisation. The skills of existing and specially recruited research staff from the Floreat Park and North Ryde laboratories (of the then Divisions of Minerals and Geochemistry, and Mineral Physics and Mineralogy, subsequently Exploration Geoscience and later Exploration and Mining) were integrated to form a task force with expertise in geology, mineralogy, geochemistry and geophysics. Several staff participated in more than one project. Following completion of the original projects, two continuation projects were developed.

P240A: Geochemical exploration in complex lateritic environments of the Yilgarn Craton, Western Australia (1991-1993). Leaders: Drs R.E. Smith and R.R. Anand.

The approach of viewing geochemical dispersion within a well-controlled and well-understood regolith-landform and bedrock framework at detailed and district scales continued. In this extension, focus was particularly on areas of transported cover and on more complex lateritic environments typified by the Kalgoorlie regional study. This was supported by 17 companies.

P241A: Gold and associated elements in the regolith - dispersion processes and implications for exploration. Leader: Dr. C.R.M. Butt.

The significance of gold mobilisation under present-day conditions, particularly the important relationship with pedogenic carbonate, was investigated further. In addition, attention was focussed on the recognition of primary lithologies from their weathered equivalents. This project was supported by 14 companies.

Although the confidentiality periods of the research reports have expired, the last in December 1994, they have not been made public until now. Publishing the reports through the CRC LEME Report Series is seen as an appropriate means of doing this. By making available the results of the research and the authors' interpretations, it is hoped that the reports will provide source data for future research and be useful for teaching. CRC LEME acknowledges the Australian Mineral Industries Research Association and CSIRO Division of Exploration and Mining for authorisation to publish these reports. It is intended that publication of the reports will be a substantial additional factor in transferring technology to aid the Australian Mineral Industry.

This report (CRC LEME Open File Report 70) is a Second impression (second printing) of CSIRO, Division of Exploration Geoscience Restricted Report 187R, first issued in 1991, which formed part of the CSIRO/AMIRA Project P241.

APPENDIX A

A. SAMPLE DESCRIPTIONS

The following section contains brief notes on the hand-specimen samples of gossan and weathered rock which have been studied in the course of this project, and comprises part of the data set. The notes are intended to be read in association with the illustration of the particular sample which is at the macro-scale,

the photographs however do not necessarily illustrate all features of the sample, particularly the spatial relationships. The key to the illustration follows the sample number in description [for more convenient use in general reference the illustrations are given in sequence of the sample reference number].

The term 'grain' is used for gold to imply that structure/form/habit is not defined, and '?' is used as a prefix qualifier to indicate probability rather than certainty; 'oxide' should be taken to mean 'undefined iron-oxides'.

A.1 West Limb - surface gossan.

The general nature of the topography and outcrop is shown in Plate 2. The vegetation is principally native grasses with some very few scattered shrubby-acacia.

67016 [3-2]

The sample is largely siliceous with vuggy quartz, the more massive quartz is translucent. Overgrowths of botryoidal silica are present. No visible gold, but one 400 micron grain of native copper occurs in an iron-oxide matrix.

67046 [3-3]

The specimen is largely after sulfide, with some quartz on the edge. The boxworks are not completely infilled and it carries a meshwork of yellow to orange-brown porcellanic silica, and rare transparent quartz. No visible gold.

67047 [3-4]

This is massive red-black oxide without visible structure, but it carries hard black 'octahedral' pseudomorphs, not pyritohedra, and rare transparent quartz. Visible gold is common on broken surfaces, generally as flattened grains of 200 to 500 micron. There is iridescence on some surfaces, this is polychromic, from yellow through violet, and is not desert varnish (it is similar to that on certain near-surface Mt Morgan gossans).

67048 [4-1]

The sample consists of oxide after large sulfide aggregates, about 10mm, in a quartz matrix. The boxworks are generally not completely infilled. The oxides vary in color from yellow to red-brown. The quartz is not clear and there are no visible terminations. Some vugs contain very small amounts of unidentified secondary minerals. One gold grain, 200 micron, was observed in a cast after sulfide, attached to quartz.

67050 [4-2]

This is an open boxwork of oxide and silica with veins of red porcellanic silica; some terminated micro-quartz occurs in vugs. There are a few deep-red oxide pseudomorphs after pyritohedra, with iridescence on some surfaces. Visible gold, around 100 micron, is common in pseudomorphs after pyrite.

67051 [4-3]

The sample consists of massive quartz and open boxworks after pyrite, transparent quartz is rare. Some boxworks have an unusual platey habit. It carries visible gold; one grain is platey, around 20 micron, and is between the wall plates of a boxwork. A second, some 500 micron, is attached to quartz in a 'vug' after sulfide. Some surfaces are iridescent.

67052 [4-4]

The material consists essentially of boxworks after sulfide which are largely infilled, there are also some very thin veins of red-brown quartz. On broken surfaces it has a platey appearance with the more massive oxides an iron-grey. The quartz is mostly translucent. Visible gold occurs as paint on quartz and as 20 to 50 micron particles on the walls of open boxworks.

67053 [5-1]

The sample is pervasively quartz-veined, the quartz is translucent but clear terminated crystals are seen in vugs. The oxide ranges from semi-open box-works, yellow-brown to brown in color, to massive dark pseudomorphs. There is much botryoidal oxide, with some almost vitreous. Very rare green secondary minerals were observed together with an unidentified colorless phase. One grain of gold, 10 micron, was seen attached to a boxwork wall and a small grain of native copper adjacent to green secondary minerals.

67054 [5-2]

This is a rather massive ironstone, but evidently after sulfide, some fractures are conchoidal with a grey color. It carries pseudomorphs after pyritohedra with some association with micro terminated-quartz. There are a few 'grains' of clear quartz but most is translucent. One small area of micro-vugs contains apple-green secondary micro-crystallites whilst a second area carries very pale green and colorless secondaries. Gold is common on cut and broken surfaces, generally 20 - 50 micron, but one larger grain is some 400 micron in size.

67055 [5-3]

A massive ironstone with a micaceous contact. There is indication of geometric pseudomorphs in the massive oxide and 'vugs' after pyritohedra in the micaceous selvedge. It also carries quartz, mostly translucent, but a little is clear and all is fractured. There are some inclusions of clay. Some little paint gold is visible, together with one grain of 500 micron in a small quartz vein adjacent to oxide after sulfide.

67056 [5-4]

This sample represents a quartz vein with open and infilled boxworks after sulfide, the oxide is red to yellow-red. The quartz carries a number of armoured grains of sulfide, ?pyrite. The boxworks contain powdery or porous residues together with fibrous and botryoidal oxide, suggesting oxidation in a perched position. There are several blebs of pale green secondaries in/on quartz and more in one boxwork after a 7mm sulfide grain. Gold is seen in the form of two grains, 20 and 200 micron, of flattened habit on oxide surfaces contiguous with quartz.

67057 [6-1]

A rather massive ironstone carrying some quartz. The precursor was likely vuggy and there is indication of quartz termination. An armoured grain of pyrite is present in quartz, a little of which is clear. Some iron oxide is pseudomorphic and oxide includes very dense black 'vitreous' oxide in addition to botyroidal and platey habits.

67058 [6-2]

This is a generally massive iron oxide against ?siltstone. There is some quartz veining, mostly translucent but a little is clear. The dense iron oxides are notably bright and abut an area of open boxwork. Several grains of gold, 100 - 200 micron, are in vuggy quartz against the siltstone margin. Another grain, 100 micron, is attached to the wall of a boxwork adjacent to a quartz vug containing clear 500 micron terminated quartz.

67059 [6-3]

This sample is a particularly dense ironstone with no visible structure, it is tough and develops a high polish on sawing. There is very little quartz and fracture is 'conchoidal'. One gold grain is exposed on a fracture surface, as seen it is pyramidal with an exposed side of 1.5mm, as if initially bounded by euhedral pyrite.

67060 [6-4]

This sample is very similar to 67058. It carries one grain of a rather red gold in a semi-open boxwork after a sulfide grain of 3-4mm.

67061 [7-1]

This was part of a very large specimen which was pervasively and particularly auriferous. The sub-sample is mostly red-black indurated oxide with areas of boxwork containing sinter, against a 'clayey sandstone', presumably siltstone. The oxide carries some few yellow or red porcellanic veinlets which seem to be associated with much of the visible gold. Several 50 micron grains occur along the side of such a veinlet together with two 300 micron 'blobs'. A 400 micron 'dumbbell' was seen in a siliceous area adjacent to a boxwork. The sample also has areas of boxwork with a rhomboidal pattern (Plate 3), which is ascribed to carbonate which was clearly well defined with large crystals. The webwork of these cells is essentially siliceous.

67062 [7-2]

This specimen is a relatively light weight porous sponge with largely porcellanic boxwork walls but also with the more usual oxide structures. Sinter is abundant. The structure is intersected with a few red porcellanic veinlets. Some small

gold grains, 20 to 50 micron were seen on siliceous boxwork walls and on a siliceous webwork.

67063 [7-3]

This is derived from a larger quartz vein, carrying in part discrete sulfide grains. There are pseudomorphs after pyrite. Discrete secondary minerals are rare with one 500 micron area of green micro-crystallites in a boxwork in vuggy quartz. A 1mm 'blob' of native copper occurred in a vug containing larger, 1mm, terminated quartz. Gold was seen as a 100 micron grain on the wall of a box-work and as a 300 by 400 micron grain in pseudomorphic oxide in a vuggy zone.

67064 [7-4]

The sample is derived from a massive sulfide, quartzose precursor. The quartz is generally translucent and carries pseudomorphs after sulfide. In vuggy areas the quartz is micro-terminated. Some red porcellanic silica is present. The oxide consists of open and infilled boxworks, some of which carry sinter. Visible gold occurs as a 300 micron particle in a vuggy zone, and as a number of 50 to 100 micron particles, adjacent to red silica. These latter appear to be aggregates, or dendritic structures.

67065 [8-1]

This is a gossan against a contact of ?siltstone. It contains vuggy siliceous areas containing micro-crystals of quartz and areas of porcellanic silica. Oxides are in the form of massive pseudomorphs after sulfide and of boxworks. Much of the boxwork web has the unusual platey nature. Gold is found as 100 to 300 micron particle in areas of vuggy silica and in vugs within oxide. There is a little paint gold on oxide fracture surfaces and a 20 micron particle in a red oxidic pseudomorph.

67066 [8-2]

The sample is derived from massive sulfide with limited quartz veining. It consists of boxworks in varying stages of infilling together with areas of more solid pseudomorph. Silica ranges in type from opaque to smaller clear crystals and some 'waxy' silica on surfaces. Gold occurs as 20 to 100 micron particles within boxworks but with one at some 400 micron, and with a 20 micron particle within an oxide pseudomorph. One 300 to 400 micron particle is intergrown with clear quartz in a vug exposed on a broken surface.

67067 [8-3]

The gossan consists largely of a boxwork system with a high proportion of siliceous web-work, and containing zones of leached clay. The siliceous web appears to be largely secondary silica, at least partly botryoidal. It is notable that a significant

proportion of the boxwork possesses parallel webs, after ?carbonate. One 50 micron particle of gold is seen in an area of siliceous boxwork.

67068 [8-4]

The sample is largely boxwork, more or less in-filled with wisps of quartz veining and with massive nondescript brown to red oxide. Cream to red porcellanic silica veining is common. A proportion of the boxwork is 'rhomboidal'. The sample carries a very small quantity of white secondary minerals. No gold was observed.

67069 [9-1]

This is part of a translucent quartz vein system with some pseudomorphic oxide and boxworks which are largely infilled with yellow to orange oxide. Clear quartz is rare but vugs carry unusually large terminated crystals (with reference to this locality).

67070 [9-2]

The sample is significantly siliceous with areas of siliceous boxworks and larger amounts of red porcellanic silica. Most quartz is translucent, but there is some fragmental clear material. The upper contact is clay/siltstone. Oxide boxworks are abundant, seemingly after sulfide, but the siliceous areas are cryptic. Gold is freely visible, ranging in size from 50 to 500 micron and occurring in open boxworks and especially in the red silica. One 1mm particle occurs in the porcellan.

67071 [9-3]

This gossan has ?siltstone as an upper contact and contains a large volume of translucent quartz with secondary clear terminated crystallites. A grain of pyrite is armoured by quartz. There is a limited amount of red porcellanic silica. Open boxworks are after sulfide as are the solid pseudomorphs, however some boxworks appear to be more regular in pattern. A single 500 micron particle of gold was observed in quartz, in contact with oxide after sulfide. A similarly sized particle of copper is present in a vuggy area with subtly green secondaries covering the micro-crystals of quartz.

67072 [9-4]

The sample is largely siliceous with boxworks mostly open. There is much red porcellanic silica with terminated micro-crystals of quartz in vugs and on other surfaces. A proportion of the voids are very elongate and may be after tourmaline. One area of the gossan consists of indeterminate ochreous yellow oxide. Gold is present in the form of a 600 micron grain on a weathered surface and a 300 micron particle in a vug on a cut surface.

67073 [10-1]

The specimen is part of a larger quartz vein, carrying oxide pseudo-morphic after sulfide and semi-infilled boxworks. Some clear quartz is present with larger terminated quartz in vugs. Centimeter scale pseudomorphs are present in the quartz and occasional parallel webworks. Gold is observed as 20 to 50 micron particles on surfaces, a 50 micron particle in an open box-work and a 30 - 50 micron grain in an oxide-filled boxwork.

67074 [10-2]

The sample is somewhat siliceous, but consists mostly of boxworks, some infilled and with a larger amount of sinter, the latter tending to be localised. One small area of the boxwork carries very fine grained green secondaries together with a waxy white phase. One surface carries unexpectedly regular boxworks. Gold is present as a 500 micron particle, distinctly reddish, together with normally colored 100 and 500 micron grains. A 200 micron slug is visible on a broken surface.

67075 [10-3]

A generally dense ironstone gossan but with some boxwork and a limited area of parallel web. Pyrite striations are evident on some surfaces together with outlines of cubic pyrite. Quartz vugs carry secondary terminated micro-crystals and an unidentified pseudomorph. Boxworks also carry botryoidal silica and waxy over-growths. Gold occurs as paint on broken surfaces, as a reddish grain of 50 - 100 micron on a cut oxide surface and as gold crystals on quartz in a micro-vug.

67076 [10-4]

The sample is somewhat siliceous, with an attached quartz vein. It carries solid pseudomorphs and contiguous open boxworks, probably after 5mm pyrite. Red porcellanic silica is evident, together with a little clear quartz. Some surfaces show pyrite striations. Gold was evidenced only by metallic smears on silicic surfaces.

67077 [11-1]

A somewhat siliceous specimen with boxworks carrying ocherous oxide. Other boxworks carry secondary silica and quartz. A dubious grain of copper (too yellow), 100 - 200 micron, is visible in a silicified area. Definite gold particles of 50 - 100 micron are visible on a broken surface.

67078 [11-2]

This is an unusual specimen, apparently after a planar and extensive siliceous zone in contact with ?siltstone. It consists of parallel micro-veins of silica which may however be secondary. Both clear and red porcellanic silica occur as extensive 'webs'. Boxworks contain sinter, some almost solid, and others ocherous oxide.

Platey oxide represents pseudomorphs of an elongate phase, ?tourmaline and some voids are apparently after the same phase. There is a notably high visible gold content; the gold is generally of a flattened habit occurring in boxworks and on broken surfaces.

67079 [11-3]

An ironstone of rather dense oxide but with areas of boxwork containing sinter which suggest large, 2cm, pyritohedra. There are some small, 1mm, pseudomorphs with striations, after pyritohedral pyrite. Small secondary quartz veins contain micro-crystals of quartz. No visible gold observed.

67080 [11-4]

The sample is a quartz vein with included oxide after sulfide. The quartz is generally translucent, but carries a few clear 'grains' and small clear secondary crystals. Sulfide veining is represented by dense oxide with a conchoidal fracture. Armoured pyrite is present in quartz, and possibly a small grain of gold, 20 micron.

67081 [12-1]

A massive and dense oxide gossan with a vitreous fracture. There is a very limited development of boxworks, which are quite nondescript, but carry, in and around, a white to cream secondary phase. Native copper is present in one 400 micron particle, and slightly reddish gold particles, 300 micron, are visible on a cut surface.

67083 [12-2]

The specimen is zoned, but is, generally, open boxwork with areas of dense oxide and well developed red and yellow porcellanic silica. Some micaceous ?veinlets are present. The boxworks contain some black sinter and ocherous yellow oxide. Pseudomorphs after 4 - 6mm cubic pyrite are visible in the oxide, and a few smaller pseudomorphs in porcellan. Several particles of gold, 100 micron, are visible on web walls.

A.2 East Limb surface rock

A.2.1 creek outcrop

The nature of the outcrop at this location is shown in Plate 1. Adjacent vegetation consisted of native grasses and shrubby acacia.

67091 [14-2]

The sample is after sulfide bearing reef quartz. The quartz varies from opalescent to translucent with very little clear material. There has been substantial infilling with clay. The oxides are mostly webwork, some relatively massive, with few pseudomorphs; some oxide surfaces show very strong iridescence. Four gold particles, 200 micron, were observed on oxide in small ex-sulfide oxide veins.

67092 [14-3]

This is a rather unimpressive specimen, it is translucent vein quartz, in contact with a sandy ?siltstone and with some adherent mauve 'sand'. It carried a relatively small amount of sulfide. A small patch of paint gold is visible on an oxide surface and a 50 micron particle is attached to quartz at the edge of a small oxide veinlet.

67093 [14-4]

The specimen is an example of "disaggregated" reefal quartz, with ?siltstone and micaceous contacts. It consists of relatively small pieces of broken quartz with oxide cement. The quartz carries casts after sulfide, and voids after sulfide occur in interstices. The cement is partly solution deposited and forms a fine web structure. A few vugs contain small clear terminated quartz. Some oxide surfaces are iridescent.

67094 [15-1]

This is the upper contact siltstone, orange to mauve in color. It is somewhat micaceous, with a micro quartz vein on the broken surface; this quartz carries casts after pyrite and is generally clear. The siltstone contains casts after 3 - 4mm cubic pyrite with little residual oxide.

67095 [no illustration]

Translucent reef quartz with a siltstone contact. Clay covers most surfaces and infills some voids. A gold particle, 100 micron, is attached to quartz which also contains a small grain of armoured pyrite.

67096 [15-2]

This is a sample of more massive, translucent, reef quartz, with clear micro-crystals occurring in vugs. It is in contact with disaggregated reef quartz, and has a general clay coating. Some surfaces carry massive oxide and boxworks. Vugs in the quartz appear to have contained sulfides.

67097 [15-3]

The sample is 'massive' quartz, apparently of multiple generations, which carries casts after cubic pyrite, as do more ferruginous areas. The rock has been silicified, likely after an initial oxidation, possibly with reintroduction of pyrite.

67098 [15-4]

A contact siltstone with multiple micro-veins of quartz which is generally clear. There is an oxide coating, partly boxworks, on a broken surface and the rock carries casts after disseminated pyrite cubes, 0.2 to 1mm.

67099 [16-1]

It is a micaceous ?sandstone in contact with a coarser sandstone; it contains micro quartz veins. The rock carries sparse casts after 2mm cubic pyrite.

67156 [17-2]

The sample is reef quartz thoroughly coated and infilled with yellow-brown clay, against a ?siltstone contact. The quartz is generally opaque to translucent, but with some clearer material. It carries oxide webwork, evidently after matrix sulfide; some oxide surfaces are iridescent. The quartz contains casts after 2mm pyritohedra while the oxide shows pyrite striations. Gold was observed as a metal smear on a quartz surface and as a 600 micron wire, also on quartz.

A.2.2 East Limb surface, general

67162 [17-4]

The specimen is a macro webwork of solution deposited iron oxides, with included reef quartz. It has been infiltrated by sand and clay.

65937 [1-3]

The sample is after a sulfide bearing quartz vein, intrusive into the footwall sand-stone. There is a minimal amount of clear quartz. The oxides form web-works and solution deposited forms with some iridescence. There is a significant amount of visible gold, but all is in the form of small particles. One 30 micron grain is attached to a web on a broken surface while two lacey aggregates, 30 and 100 micron are on the surface of a micro-stalagmite.

65938 [1-4]

This is a disaggregated quartz vein, with evidence of sulfides, which is in contact with ?siltstone. The quartz varies from opalescent to translucent. Small pyrite pseudomorphs are present in the siltstone. The development of the oxides is limited, and there is only a small amount of sinter or ocherous infilling in voids, but there is black botryoidal solution-deposited oxide through-out the sample. Gold is present as paint on an oxide surface.

65939 [2-1]

The sample represents an oxidised sulfide vein in siltstone, with associated reef quartz. The present oxides are dense and the contact siltstone is somewhat ferruginised. While there is evidence of a pseudomorphic nature, principally as 4 to 5mm pyrite pseudomorphs, some oxide is solution deposited and of botryoidal habit. The quartz is generally translucent, but with some few clear particles. Reddish gold particles, 30 to 300 micron are present in oxide veinlets after sulfide.

65940 [2-2]

Similar to 65939, the sample is a dense oxide 'vein' with some quartz and in contact with ?siltstone. There is a higher proportion of clearer quartz. The siltstone carries pseudomorphs after pyrite.

65941 [2-3]

The ironstone derives from a sulfide vein with quartz reef to one side and siltstone to the other. The oxides are a combination of boxwork, largely oxide infilled, together with pseudomorphs. The siltstone carries pseudomorphs after 2 to 5mm pyrite. The included quartz is translucent.

65943 [no illustration]

The ironstone, which derives from a sulfide rich vein or zone, is almost totally a solution deposited network which now forms a sponge of black oxide. There are areas of silicic webwork with some indication of rhombic structure. Some micaceous material is included, together with 'veins' of porcellanic silica.

65944 [3-1]

This is a fairly solid ironstone within ?siltstone, with a thin quartz vein on one face. There are extensive areas of open boxworks in the quartz. The oxide represents pseudomorphs, boxwork, partly or largely infilled with dense or limonitic oxides and some solution deposited oxides with a vitreous fracture. Some areas of boxwork are suggestive of a rhombic nature, but others are after a cubic mineral. One particle of gold, 50 micron, is visible in dense pseudomorphic oxide.

A.3 East Limb - Subsurface

A.3.1 general

65935 [1-1]

The sample is a complex steel-grey sinter of laminated appearance due to the inclusion of laminated quartz. It has a contact with ?siltstone and is slightly dusted with a micaceous material. The quartz is mostly translucent with only minor amounts of clear material. The oxides appear to be completely solution deposited with no larger scale features. Botyroidal and micro-botyroidal forms are general, with some iridescence. The sample was taken from a minor fault zone.

65936 [1-2]

The material is a very fine oxide sponge with minor ?occluded quartz. The webwork of the sponge is largely or entirely solution deposited micro-botyroidal structures. The sample was taken from a minor fault zone.

67139 [17-1]

This specimen is a cross-cutting vein at the intersection with the foot-wall of the MVR. It is of a typical violet-grey color and comprises disaggregated quartz at the upper surface with pervasive small scale quartz veining through a leached and/or silicified quartz-clay matrix. It is quite porous with evidence of sulfide in the form of casts and solution deposited iron oxides. There is no visual evidence of gold.

67161 [17-3]

These are striated pseudomorphs of cubic pyrite, taken from the hanging-wall immediate to the MVR at RL 475.

A.3.2 East Limb - Adit 1

These samples have not been included in the photographic record due to their general lack of distinctive features at the macro-scale.

65945

The sample is buff colored 'leached clay' of low density which is transected by a very few narrow white secondary veins.

65942

The sample consists of brown to black cherty iron oxide and opalescent quartz fragments in association with an orange-ocherous leached clay. The massive iron oxide was taken as the working sample.

65946

The sample is a brown-buff 'leached clay' which carries broken pieces of reef quartz with vugs which contain very little or no oxide after sulfide. One included fragment consists of a 5mm thick oxide vein with a very narrow transecting quartz vein against a sandy contact. Some of this quartz is clear and the oxide is in part pseudomorphic or micro-boxwork. There are minor oxide pseudomorphs in the 'sand' of the contact and gold is visible in an oxide lined boxwork (200 micron), and on a broken oxide surface.

65949

This is a 'leached clay' of cobalt pink color. There are some few small transecting quartz veins with attached micro-boxwork iron-oxide after sulfide.

65948

The sample is broken and vuggy reef quartz with included and attached violet-pink sandy clay against a white talcose layer. Some quartz is laminated, with micro-boxworks on surfaces of broken quartz and in vugs. The boxwork is after sulfide with oxide webs.

65950

The material consists of broken pieces of vuggy reef quartz. The vugs contain small terminated quartz crystals and ocherous to violet- brown iron oxides. Some of the quartz surfaces carry clean casts, after carbonate or sulfide.

65947

This is a white 'leached clay' with some narrow pink sandy zones containing pseudomorphs indicating a small sulfide content. The surfaces are talcose.

A.4 West Dome

67084 [12-3]

A dense ironstone, with some little included quartz, against a micaceous contact. There are small areas of boxwork, and striations after pyrite on some oxide surfaces. The micaceous layer contains pseudomorphs after small pyritohedra.

67085 [12-4]

The sample is an oxide zone within micaceous ?siltstone. There is a small area of boxwork which contains a 50 micron particle of gold. Pyritohedral pseudomorphs occur at the contacts and in the siltstone. Areas of the massive oxide are iridescent.

67086 [13-1]

The sample is very similar to 67085.

67087 [13-2]

The specimen consists of pyritohedral pseudomorphs in a micaceous ?siltstone. There appears to have been size grading of the pyritohedra.

67088 [13-3]

The sample is very similar to 67085.

67089 [13-4]

The matrix is a micaceous ?siltstone which grades into ?sandstone, and contains a small vein of translucent quartz. The siltstone carries pseudomorphs of both cubic and pyritohedral pyrite. The sandy layer shows only casts.

67090 [14-1]

The gossan is composed of multiple webs and solution deposited oxide in contact with a partly ferruginised ?sandstone. Some quartz is included in the oxide.

A.5 Fallows Field

67135 [16-2]

The sandstone carried disseminated pyrite and was intersected by micro-quartz/sulfide veins. The sandstone is moderately ferruginised, but now contains only casts after the pyrite, (present in both habits). The veinlets however carry pseudomorphic oxide.

67136 [16-3]

The sample is a fine ?sandstone with some quartz veinlets and casts after sulfide. It is zoned with respect to the nature of the casts. The base zone carries rather nondescript casts and some solid, pseudomorphic, oxide, the central zone carries casts after pyrite cubes of 2 to 4mm whilst the upper zone carries casts after cubic pyrite and after an elongate mineral. It is unlikely that this was elongate pyrite, perhaps tourmaline.

67137 [16-4]

This is a rather dense iron oxide which is very fine grained and is featureless except for color zonation which may be a Liesegang pattern. The color is generally red-brown with a yellow pattern. It is not attractive as an active ironstone and appears to be replacement of a claystone.

APPENDIX C

CHART SEQUENCE 1

Weathered Rock - Summary Data

Key to series numbers.

1 through 37 - West Limb gossan

Appendix B - Table 1.

39 through 47 - East Limb MVR creek exposure gossan

Appendix B - Table 2.

49 through 60 - East Limb surface rocks

Appendix B - Table 2.

62 through 68 - East Limb Adit-1

Appendix B -- Table 2.

71 through 81 - West Limb Pit-4 weathered rocks

Appendix B - Table3.

83 through 89 - E-1 Reef samples, weathered rock

Appendix B - Table 3.

91 through 97 - West Dome gossan

Appendix B - Table 3.

99 through 101 - Fallows Field weathered rock

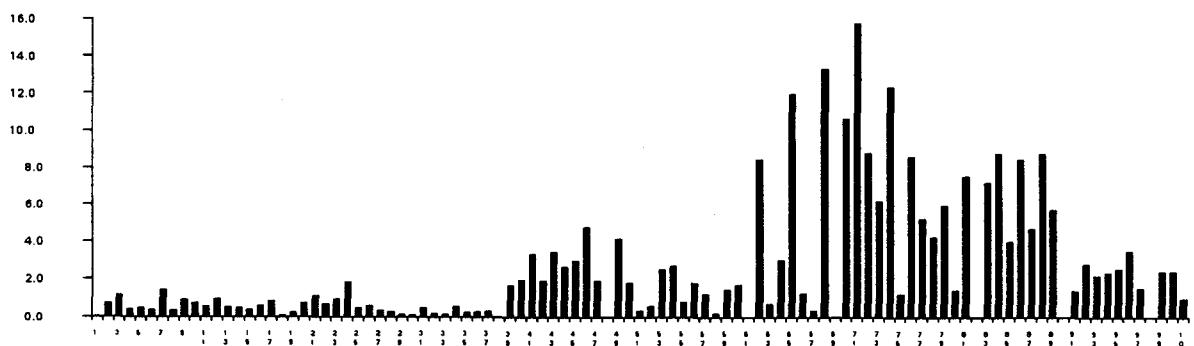

Appendix B - Table 3.

Elements shown:

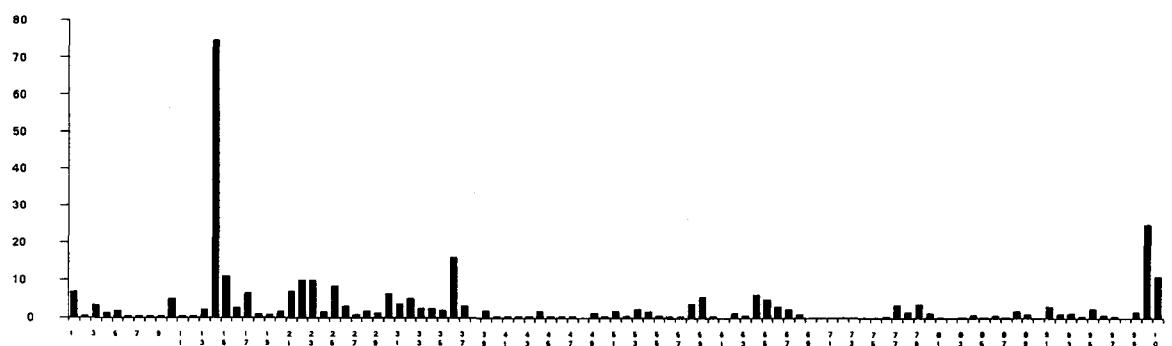

Ag	Ca	Fe	Na	S	Ti	Zn
Al	Ce		Ni	Sb	Th	Zr
As	Co	Mg	P	Sc	U	
Au	Cr	Mn	Pb	Si	V	
Bi	Cu					W

Appendix C
Weathered rock and gossan - Summary Data

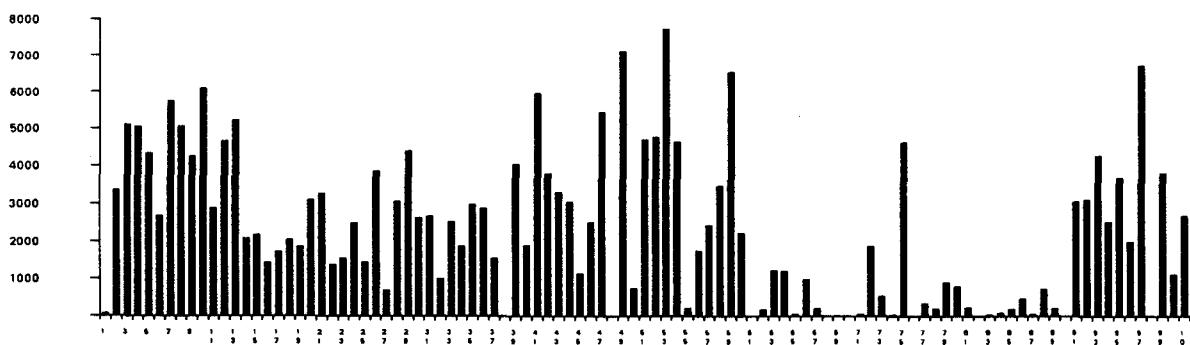

Aluminium

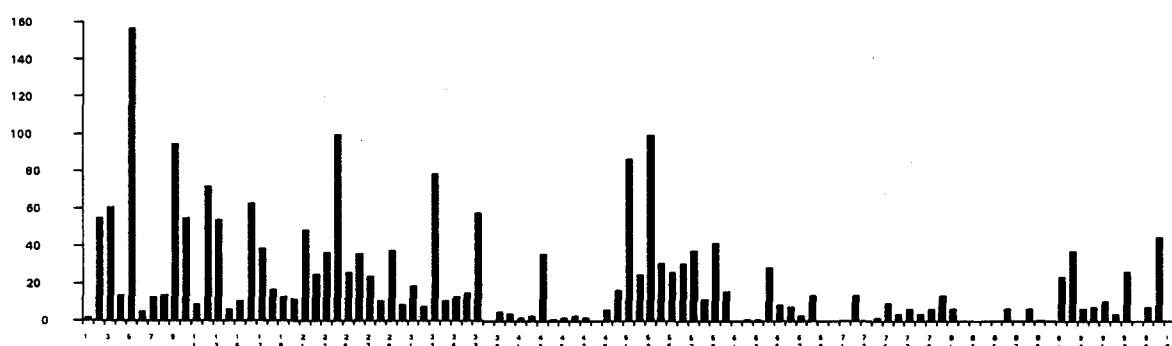

Antimony

Arsenic

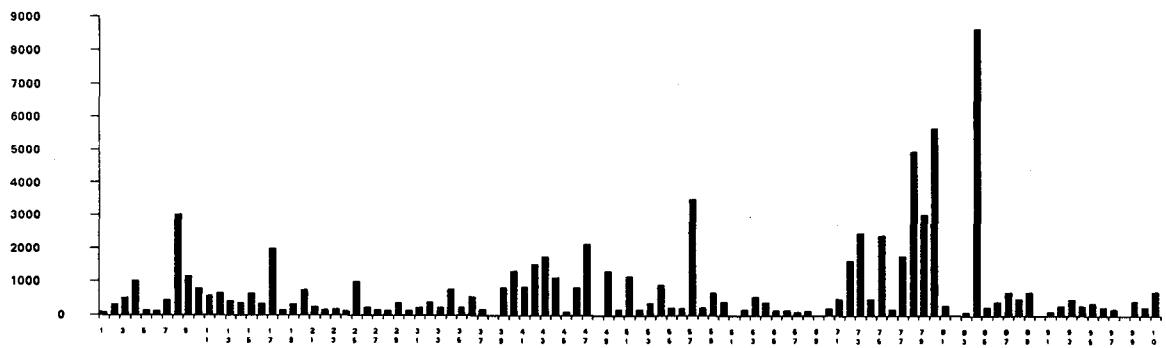

Bismuth

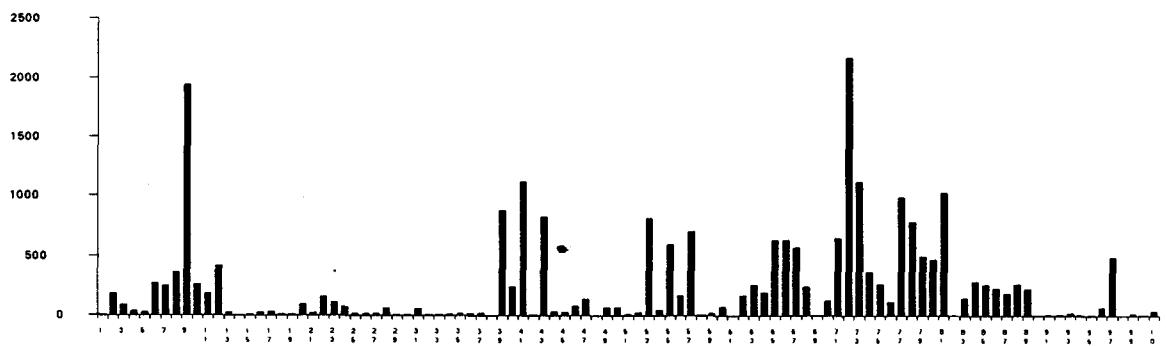

1 - 37 West Limb gossan	39 - 47 East Limb creek exposure	49 - 60 East Limb surface rocks
62 - 68 East Limb Adit-1	71 - 81 West Limb Pit-4	83 - 89 E-1 Reef
91 - 97 West Dome gossan	99 - 101 Fallows Field	

Appendix C
Weathered rock and gossan - Summary Data

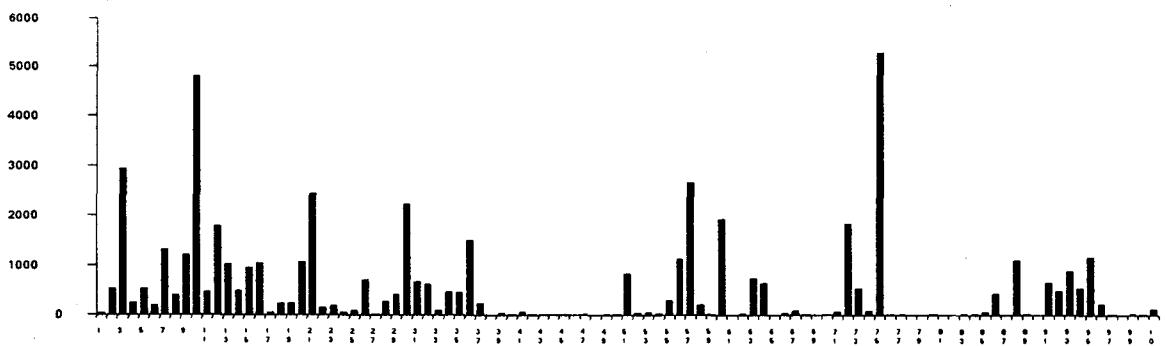

Calcium

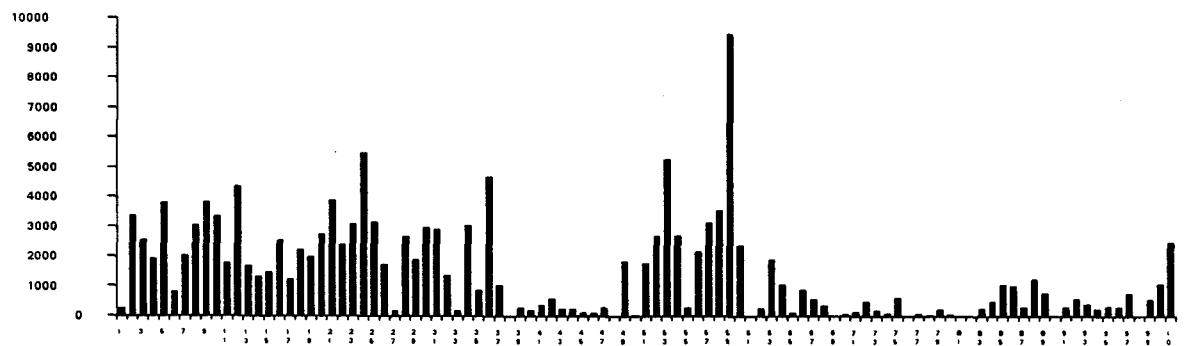

Cerium

Cobalt

Copper

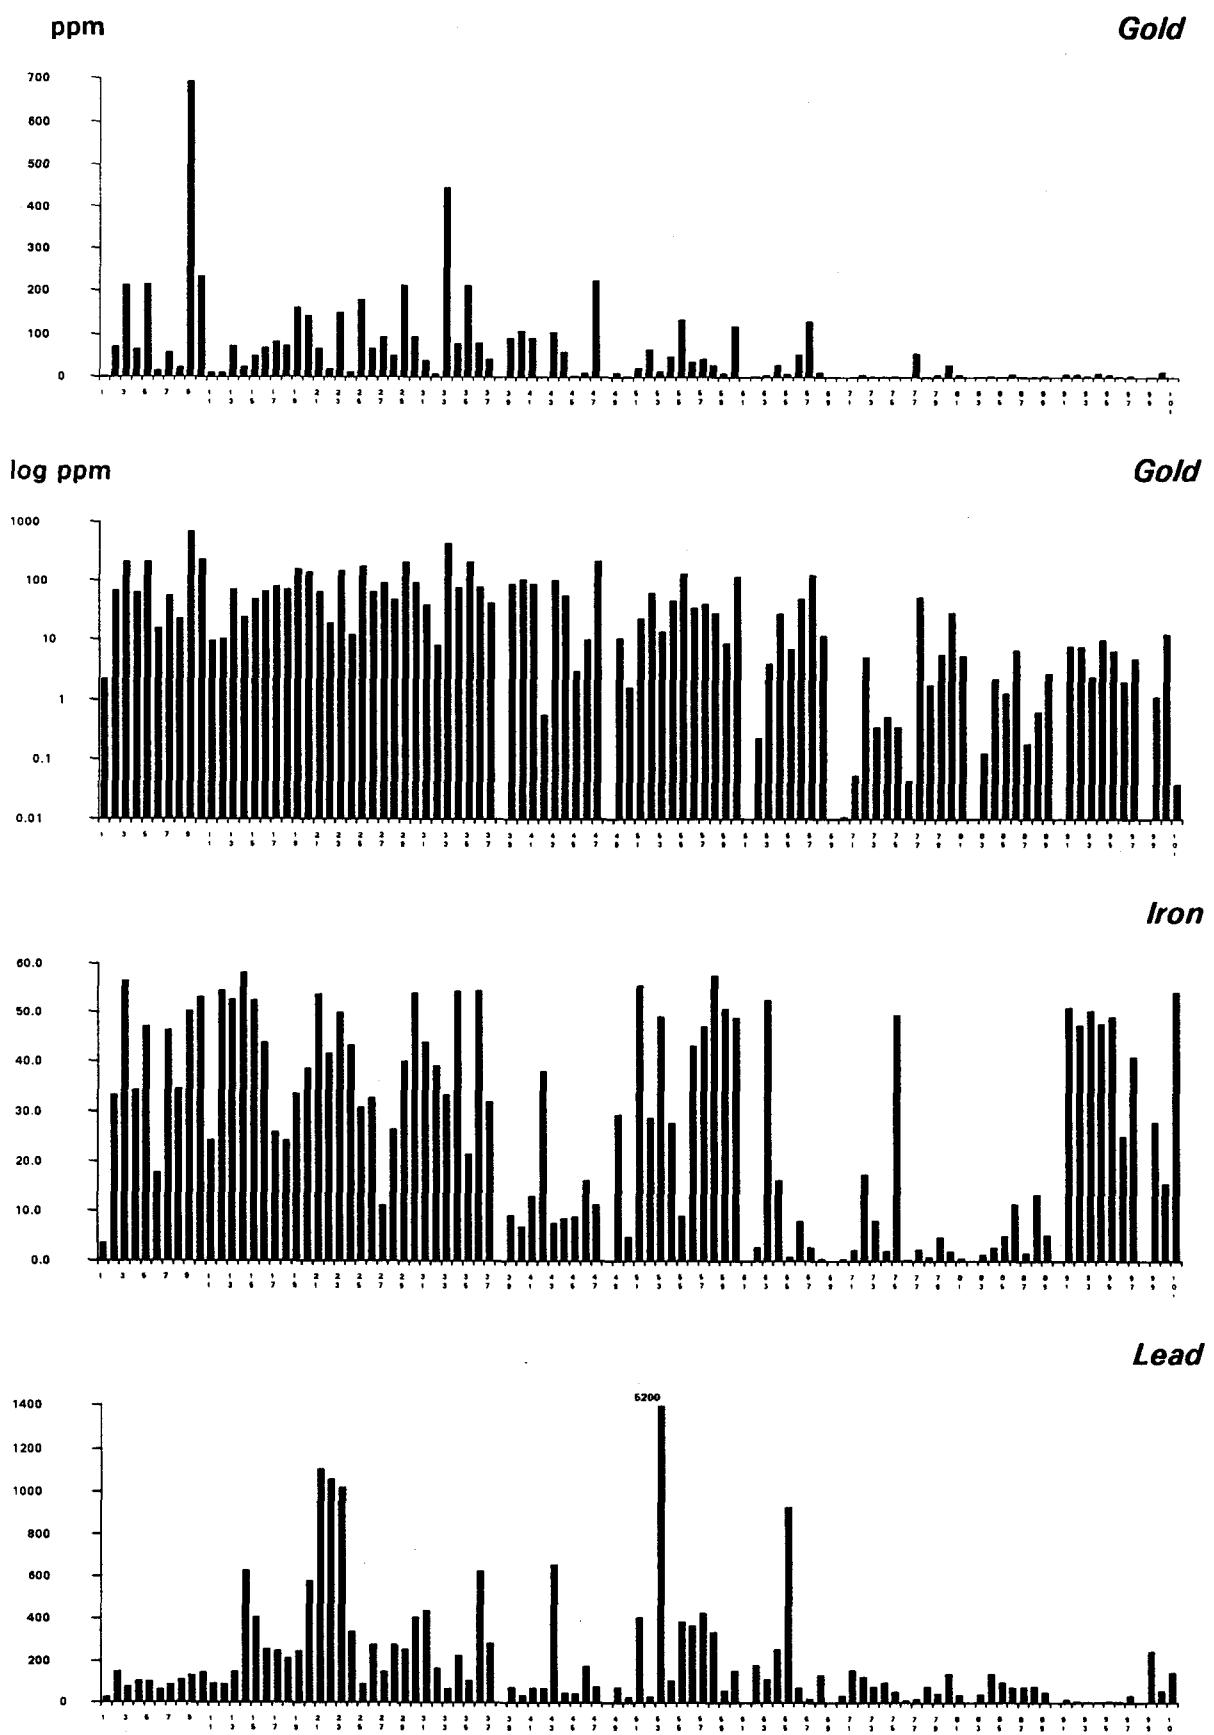

1 - 37 West Limb gossan
62 - 68 East Limb Adit-1
91 - 97 West Dome gossan

39 - 47 East Limb creek exposure
71 - 81 West Limb Pit-4
99 - 101 Fallows Field

49 - 60 East Limb surface rocks
83 - 89 E-1 Reef

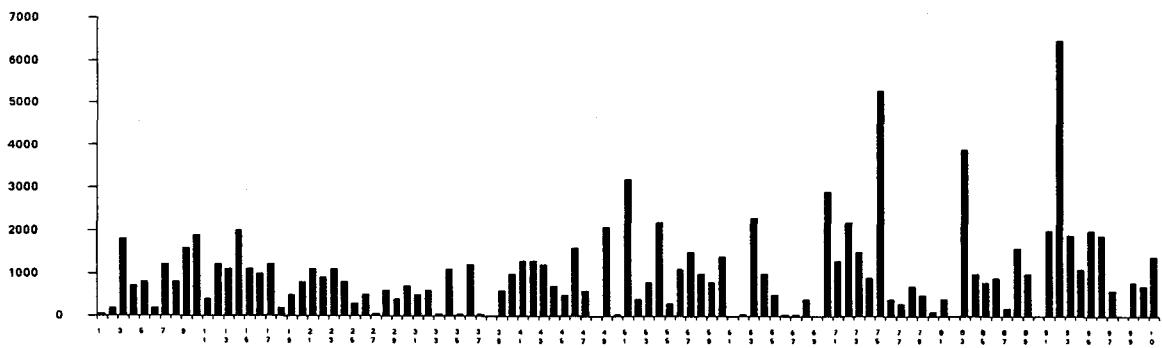

Appendix C
Weathered rock and gossan - Summary Data

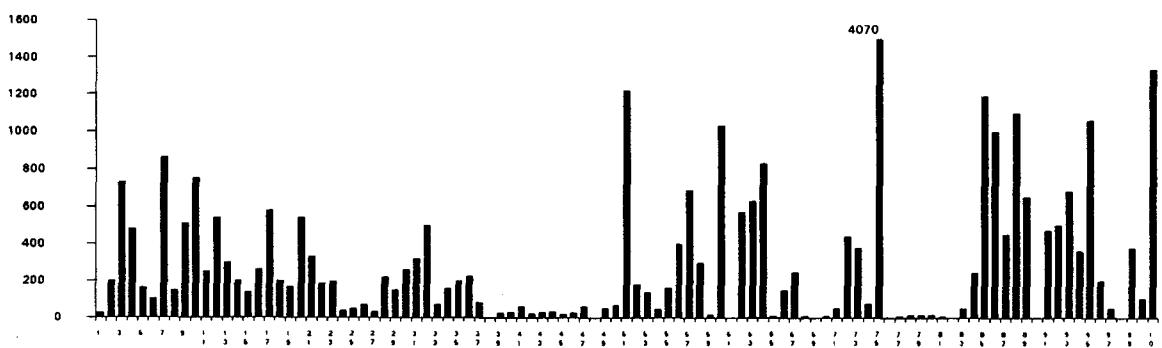

1 - 37 West Limb gossan	39 - 47 East Limb creek exposure	49 - 60 East Limb surface rocks
62 - 68 East Limb Adit-1	71 - 81 West Limb Pit-4	83 - 89 E-1 Reef
91 - 97 West Dome gossan	99 - 101 Fallows Field	

Appendix C
Weathered rock and gossan - Summary Data

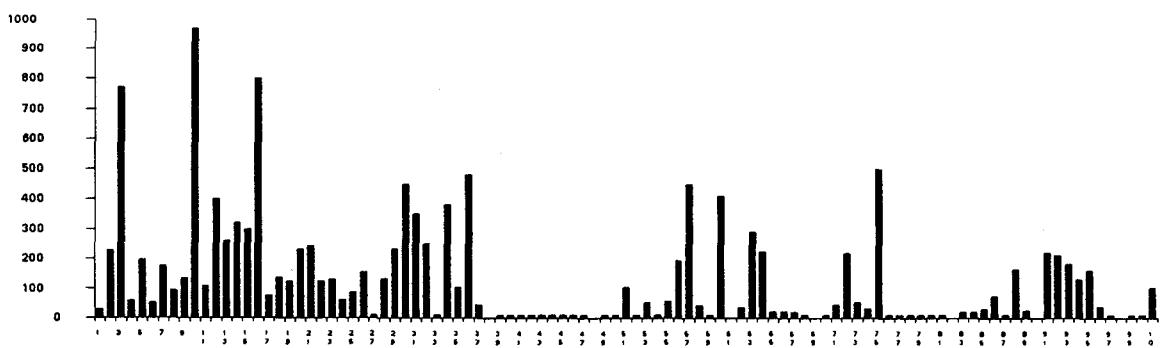

Magnesium

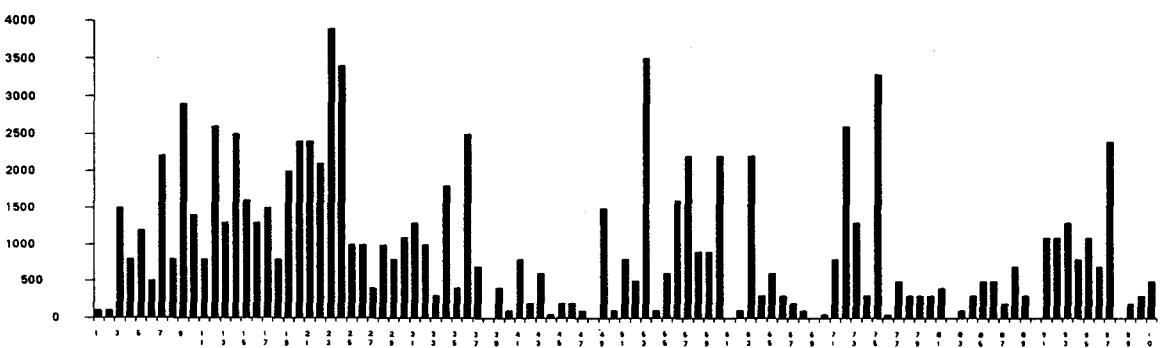

Manganese

Nickel

Phosphorus

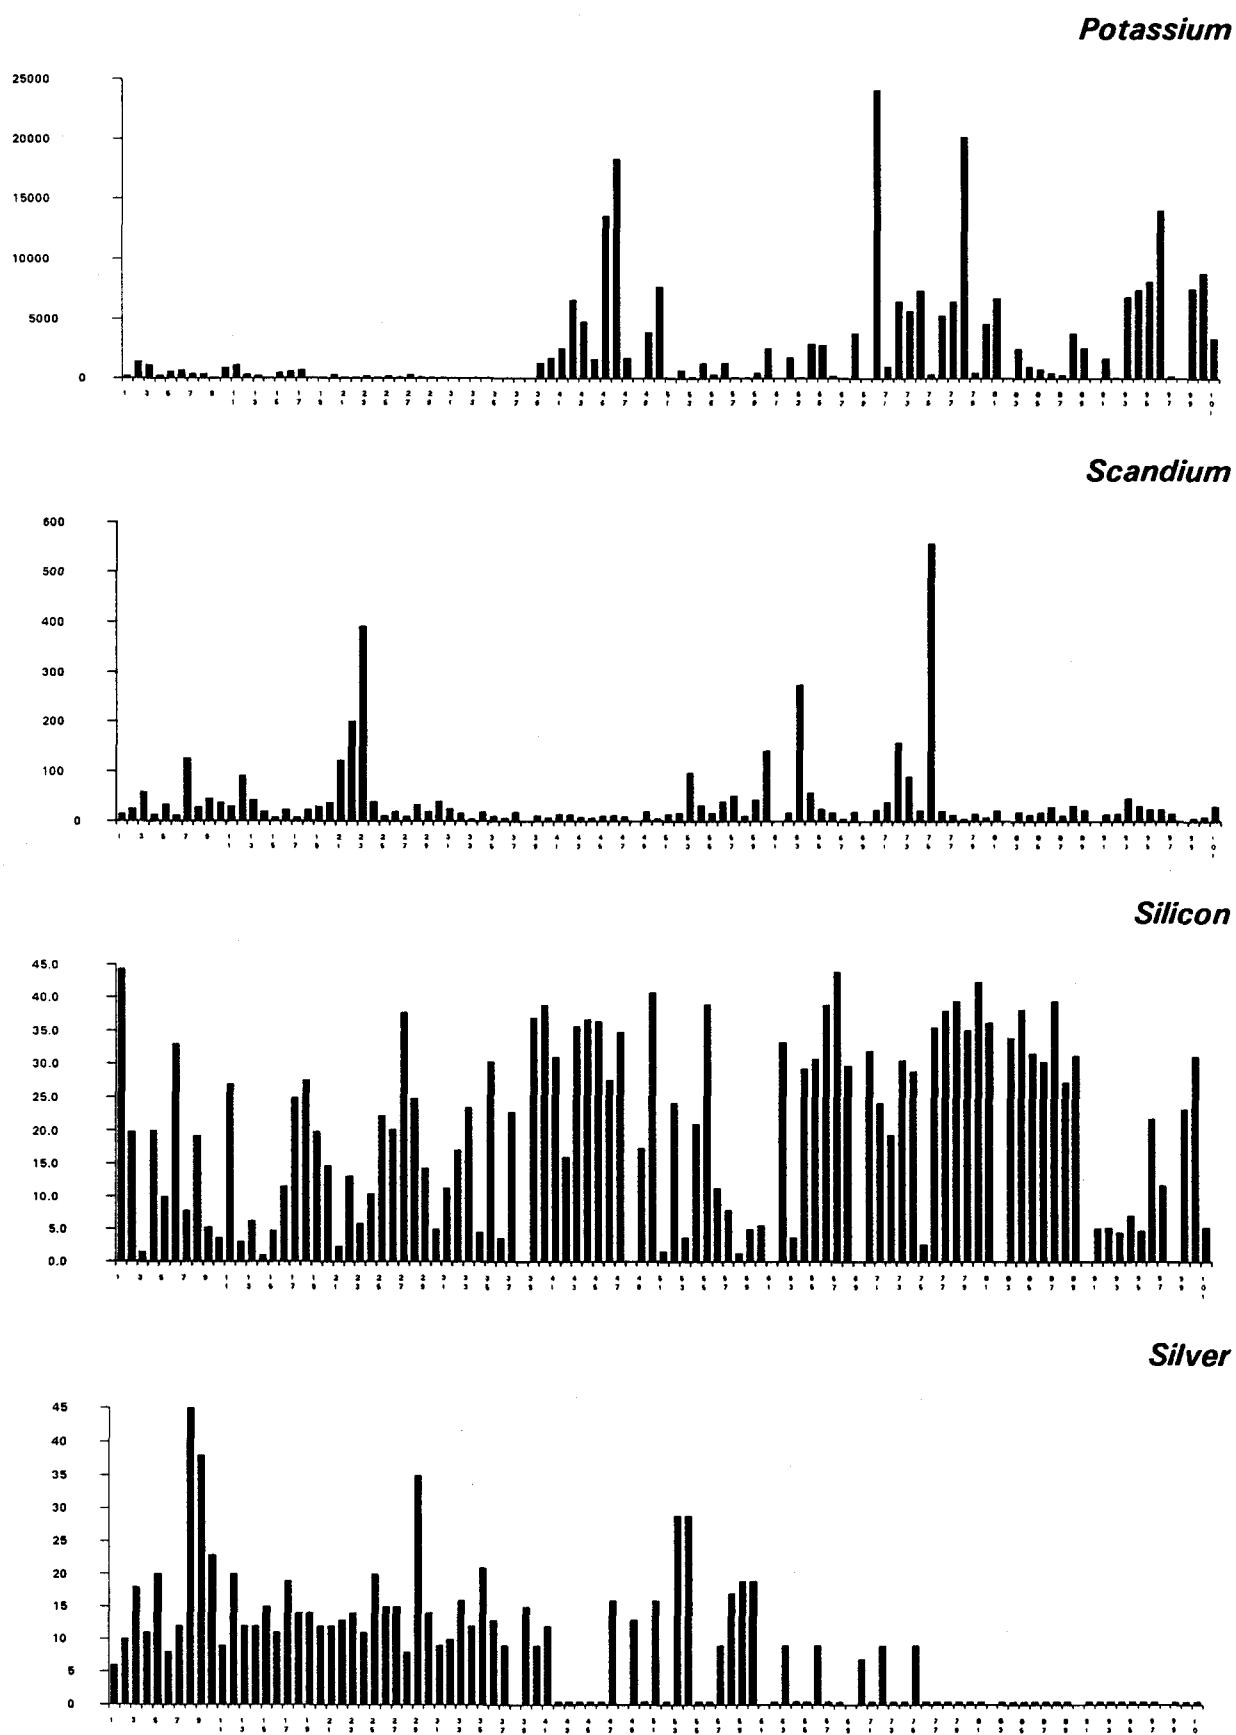

1 - 37 West Limb gossan
62 - 68 East Limb Adit-1
91 - 97 West Dome gossan

39 - 47 East Limb creek exposure
71 - 81 West Limb Pit-4
99 - 101 Fallows Field

49 - 60 East Limb surface rocks
83 - 89 E-1 Reef

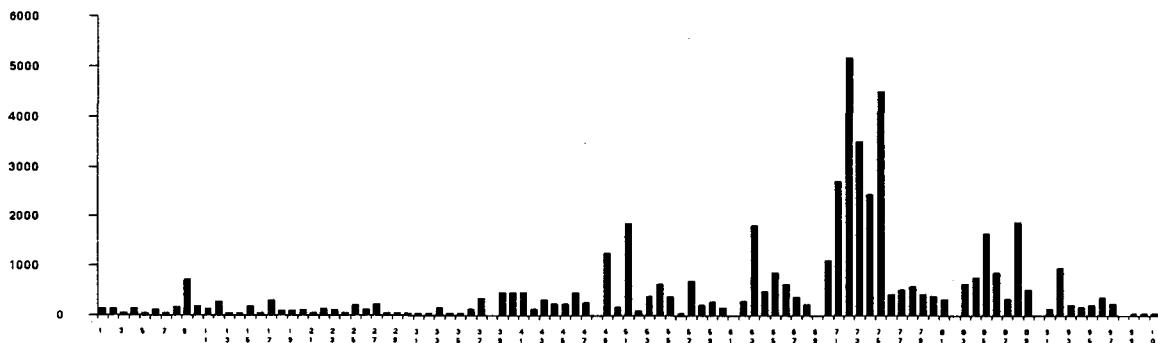

Appendix C
Weathered rock and gossan - Summary Data

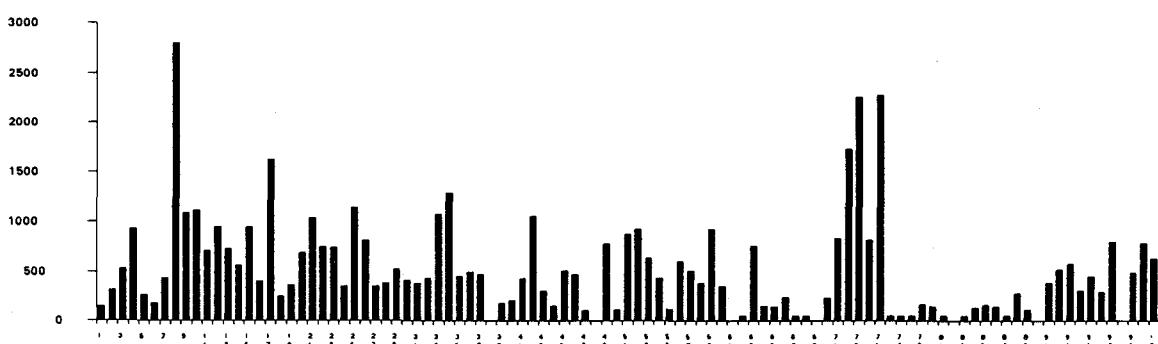

1 - 37 West Limb gossan	39 - 47 East Limb creek exposure	49 - 60 East Limb surface rocks
62 - 68 East Limb Adit-1	71 - 81 West Limb Pit-4	83 - 89 E-1 Reef
91 - 97 West Dome gossan	99 - 101 Fallows Field	

Appendix C
Weathered rock and gossan - Summary Data

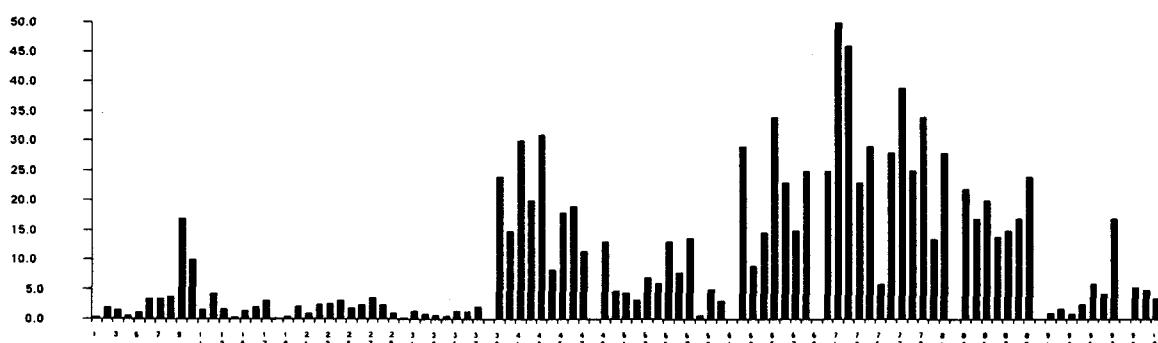

Sodium

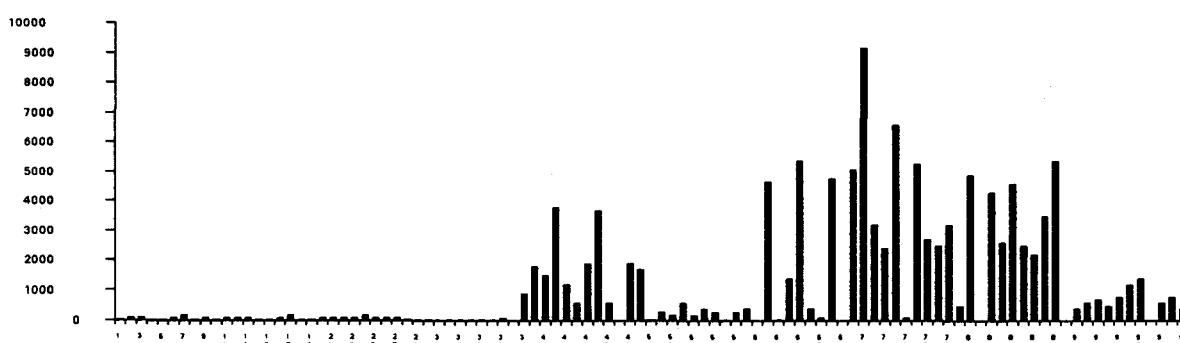

Sulfur

Thorium

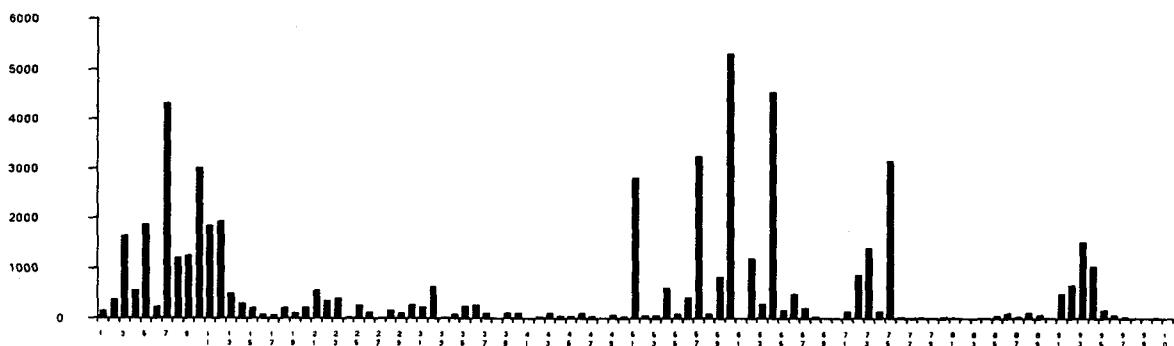

Titanium

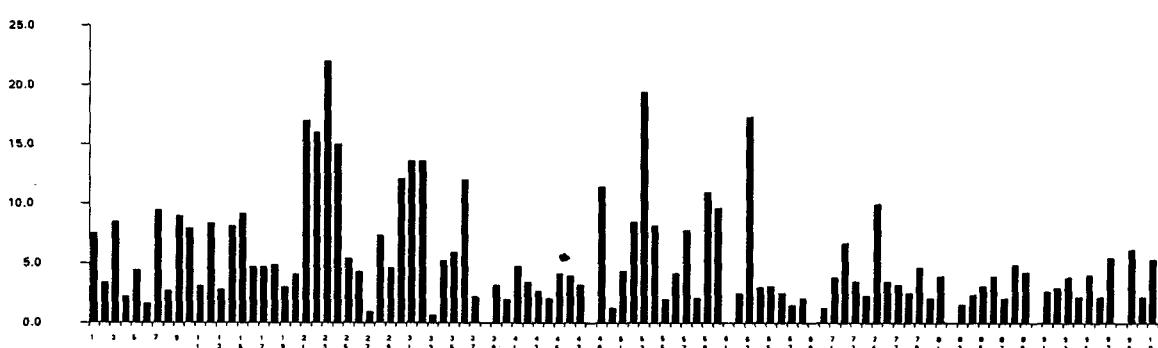

1 - 37 West Limb gossan	39 - 47 East Limb creek exposure	49 - 60 East Limb surface rocks
62 - 68 East Limb Adit-1	71 - 81 West Limb Pit-4	83 - 89 E-1 Reef
91 - 97 West Dome gossan	99 - 101 Fallows Field	

Appendix C
Weathered rock and gossan - Summary Data

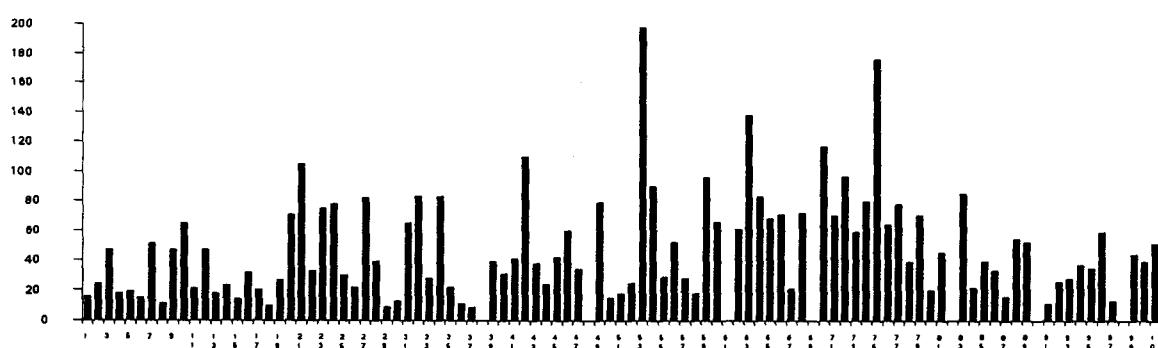

Tungsten

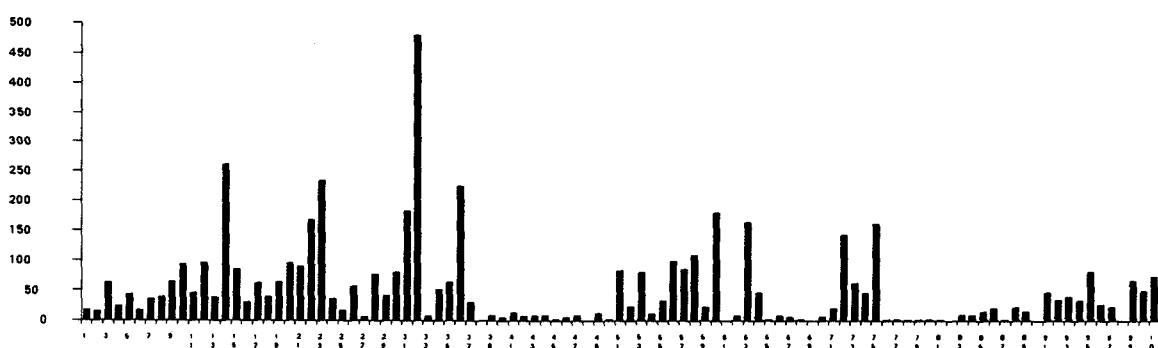

Uranium

Vanadium

Zinc

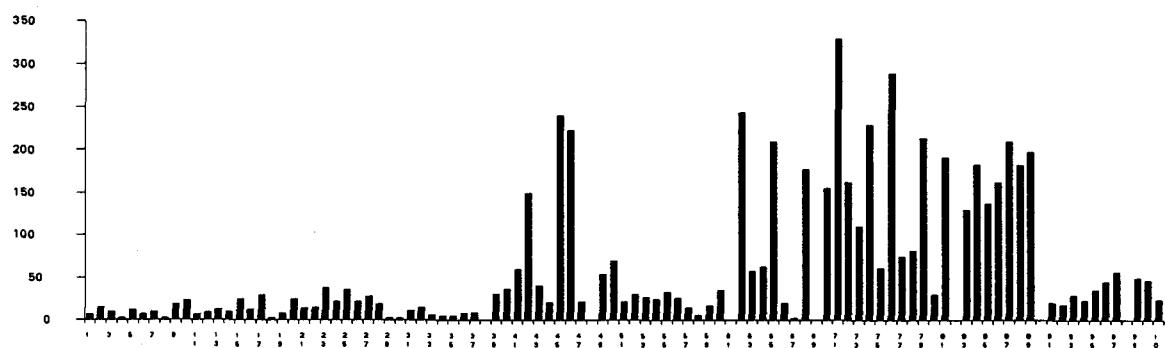

1 - 37 West Limb gossan
62 - 68 East Limb Adit-1
91 - 97 West Dome gossan

39 - 47 East Limb creek exposure
71 - 81 West Limb Pit-4
99 - 101 Fallows Field

49 - 60 East Limb surface rocks
83 - 89 E-1 Reef

Appendix C
Weathered rock and gossan - Summary Data

Zirconium

1 - 37 West Limb gossan 39 - 47 East Limb creek exposure 49 - 60 East Limb surface rocks
62 - 68 East Limb Adit-1 71 - 81 West Limb Pit-4 83 - 89 E-1 Reef
91 - 97 West Dome gossan 99 - 101 Fallows Field
